#### **CHAPTER-1**

# **INTRODUCTION**

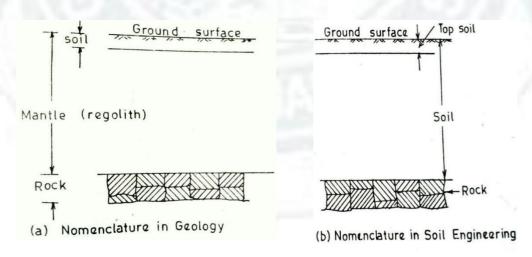

#### 1.0 INTRODUCTIONOFSOIL

The word "Soil" is derived from the Latin word solium which, according to Webster's dictionary, means the upper layer of the earth that may be dug or plowed specifically, the loose surface material of the earth in which plants grow. The abovedefinition of soil is used in the field of agronomywhere the main concern is in the use of soil for raising crops.

In geology, earth's crust is assumed to consist of unconsolidated sediments, called mantle or regolith, overlying rocks. The term 'soil' is used for the upper layer of mantle which can support plants. The material which is called soil by the agrono

layerofmantlewhichcansupportplants. Thematerial which is called soil by the agrono mist or the geologist is known as top soil in geotechnical engineering or soilengineering. The top soil contains a large quantity of organic matter and is not suitable as a construction material or as a foundation for structures. The top soil is removed from the earth's surface before the construction of structures.

Theterm'soil'inSoilEngineeringisdefinedasanunconsolidatedmaterial,composed or solid particles, produced by the disintegration of rocks. The void spacebetween the particles may contain air, water or both the solid particles may containorganic matter. The soil particles can be separated by such mechanical means asagitationinwater.

### Fig.showsacross-

sectionthroughtheearth's surface.indicating the nomenclature used in geology, and in Soil Engineering.

#### 1.1 SOILANDSOILENGINEERING:-

Theterm'soilmechanics' wascoinedbyDr. KarlTerzaghiin1925whenhisbookErdbaumechaniconthesubjectwaspublishedinGer man.

According to Terzaghi, 'Soilmechanics is the application of the laws of mechanics and hydraulics to engineering problems dealing with sediments and other unconsolidated accumulations of solid particles produced by the mechanical and chemical disintegration of rock, regarding of whether or not they contain an admixture of organic constituents.

Soil mechanics is, a branch of mechanics which deals with the action of forcesonsoiland with the flow of waterinsoil.

The soil consists of discrete solid particles which are neither strongly bonded as insolids nor they are as free as particles of fluids. Consequently, the behavior of soil issomewhat intermediate between that of a solid and a fluid. It is not, therefore, surprising that soil mechanics draws heavily from solid mechanics and fluid mechanics. As the soil is inherently a particulate system. Soil mechanics is also called particulate mechanics.

# DEFINITION OF SOIL ENGINEERING AND GEOTECHNICALENGINEERING:-

SoilEngineeringinanappliedsciencedealingwiththeapplicationsofprinciples of soil mechanics to practical problems. It has a much wider scope thansoil mechanics, as it details with all engineering problems related with soils. Itincludes site investigations, design and construction of foundations, earth-retainingstructuresand earthstructures.

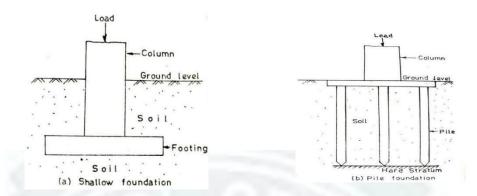

### 1.2 SCOPEOFSOILMECHANICS:-

SoilEngineeringhasvastapplicationintheconstructionofvariousCivilEngineeringworks.Someoftheimportantapplicationsareasunder.

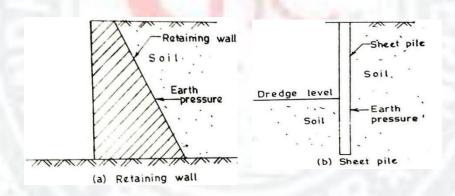

(1) **Foundations:**—Everycivilengineeringstructure, whether it is abuilding, a bridge, or a dam, is founded on or below the surface of the earth. Foundations are required to transmittheload of the structure to so il safely a ndefficiently.

Afoundationistermedshallowfoundationwhenittransmittedtheloadtoupper strataofearth. A foundation is calleddeep foundation when the loadis transmitted to strata at considerable depth below the ground surface. Pilefoundation is a type of deep foundation. Foundation engineering is animportantbranch ofsoilengineering.

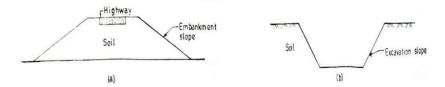

Er. ROJALI PATRA DEPT. OF CIVIL GSE, BERHAMPUR

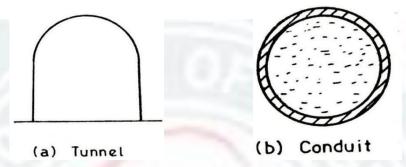

(2) **RetainingStructures:**—Whensufficientspaceisnotavailableforamassof soil to spread and form a safe slope, a structure is required to retain thesoil. An earth retaining structure is also required to keep thesoil atdifferent levels on its either side. The retaining structure may be rigidretaining wall or a sheet pile bulkhead which is relatively flexible (Fig.1.3). Soil engineering gives the theories of earth pressure on retainingstructures.

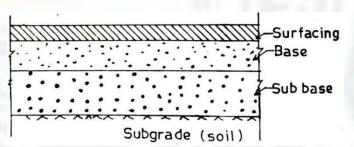

(3) **Stability of Slopes:** – If soil surface is not horizontal, there is a component of weight of the soil which tends to move it downward and thus causes instability of slope. The slopes may be natural or man-made Fig. 1.4 shows slopes in filling and cutting. Soil engineering provides the methods for checking the stability of slopes.

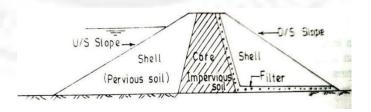

(4) **Underground structures:** – The design and construction of undergroundstructures, such as tunnels, shafts, and conduits, require evaluation offorces exerted by the soil on these structures. These forces are discussed insoil engineering. Fig. 1.5 shows a tunnel constructed below the groundsurfaceandaconduitlaidbelowthegroundsurface.

(5) **Pavement Design:** – A pavement is hard rust placed on soil (sub grade) for the purpose of proving a smooth and strong surface on which vehiclescan move. The pavement consists of surfacing, such as a bitumen layer, base and subtheme (Fig. 1.6). The behavior of sub grade under vicious conditions of loading and environment change is studied in soil engineering.

(6) **Earth Dom:** – Earth dams are the structures in which soil is used as aconstructionmaterial. Theearthdamsarebuiltforcreatingwaterreservoirs. Si ncethefailureofanearthdammaycausewidespreadcatastrophecareistakenini tsdesignandconstruction. Itrequires thorough knowledge at soilengineering.

(7) **Miscellaneous soil:** - The geotechnical engineer has sometimes to tacklemiscellaneousproblemsrelatedwithsoil.Suchassoilheave,soilsubside nce,frostheave,shrinkageandswellingofsoils.

Er. ROJALI PATRA DEPT. OF CIVIL GSE, BERHAMPUR

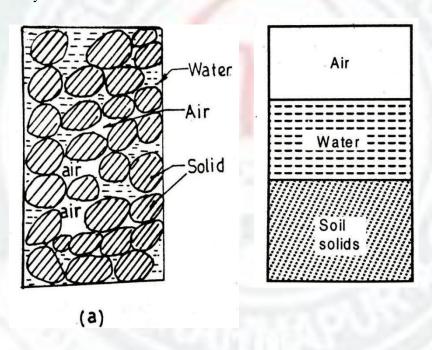

#### **CHAPTER-2**

## **PRELIMINARY DEFINATION AND RELATIONSHIP**

### **2.1 SOILASATHREEPHASE:**

A soil mass consists of solid particles which from a porous structure. Thevoids in the soil mass may be filled with air, with water or partly with air and partlywithwater.In general, a soil mass consists of solid particles, water and air. The three constituents are blended to gether to form a complex material (Fig. 2. 1.a). However, for convenience, all the solid particles are segregated and placed in the lower layer of the three-phase diagram (Fig. 2.1b). Likewise, water and air particles are placed separately, as shown. The 3-phase diagram is also known as Block diagram.

Itmaybenotedthattheconstituentscannotbe

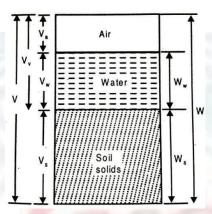

Actually segregated, as shown. A 3-phase diagram is an artifice used for easyunderstandard convenienceincalculation.

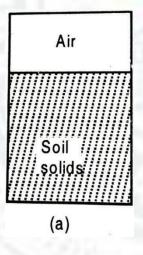

Although the soil is a three-phase system, it becomes a two-phase system in thefollowing two cases:(1) When the soil is absolutely dry, the water phase disappears(Fig. 2.2a). (2) When the soil is fully saturated three is no air phase (Fig.2.2b). It is therelative proportion of the three constituents and their interaction that governs thebehavior and properties of soils. The phase diagram is a simple, diagrammatic representation of a real soil, It is extremely useful for studying the various terms used in soil engineering and their interrelationships.

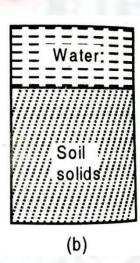

### Ina3-

phasediagramitisconventionaltowritevaluesontheleftsideandthemassontherightside (Fig. 2.3a). The mail simple of a gives soil mass in designated as V. It is equal to the sum of the volume of solids (V1), the volume of water (F) and the volume of air (Va). The volume of voids (Vv) is equal to the sum of the volumes, the water and air

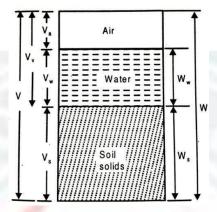

Thesoilmassofthesoil...isrepresentedasM.themassofair(ma)isverysmallandisneglecte d.Therefore,thesocialmassofthesoilisequaltothemassofsolids(M2)and the mass of water (Mw). Fig.2.36 shows the 3-phase diagram in which the weightsarewritten ontherightside.

### 2.2 WEIGHTVOLUMERELATIONSHIPS:

**WATERCONTENT:-The**watercontent(w)isdefinedastheratioofthemasswatertothe massof solids.

$$w = \frac{Ww}{Ws}$$

The water content is also known as the moisture content (m). It is expressed as a percentage, but whenever used in equation used as a decimal.

The water content of the fine-grained soils, such as silts and clays, in generallymorethanthatofthecoarsegrainedsoils, such as gravels and sands.

The water content of some of the fine-gained soils may be even more than 100%, which indicates that more than 50% of the total mass is that of water. The watercontent of a soil is an important property.

### **SPECIFICGRAVITY(G):-**

The specific gravity of solid particles (G) is defined as the ratio of the mass of a given volume of solid stothem as so fan equal volume of water at  $4^{0}$ C. Thus, the specific gravity is given by  $G = \frac{1}{100}$ 

\*Themassdensityofwaterpwat4<sup>o</sup>Cisonegm/ml,1000kg/m3or1Mg/m<sup>3</sup>.

Thespecificgravityofsolidsformostnaturalsoilsfallsinthegeneralrangeof 2.65 to 2.80, the smaller values are for the coarse-grained soils. Table gives theaverage values of specific gravity for different soils. It may be mentioned that thespecificgravityofdifferent particles in a soil mass may not be the same. Whenever

9

the specific gravity of a soil mass is indicated, it is the average value of all the solidparticles presentin thesoilmass. Specificgravity of solids is an important parameter. It is used for determination of void ratio and particle size.

Table:TypicalValuesofG

Sl.No.	SoilType	SpecificGravity
1	Grevel	2.65-2.68
2	Sand	2.65-2.68
3	Sands	2.66-2.70
4	Slit	2.66-2.70
5	InartisticClays	2.68-2.80
6	OrganicSoils	Variable,mayfallbelow2.00

Besidesthefollowingtwotermsrelatedwiththespecificgravityarealsoused.

(1) **MassSpecificGravity**(**G**<sub>m</sub>):- It isdefinedastheratioofthe massdensityofthesoiltothemassdensityofwater.

The value of the mass specific gravity of a soil is much smaller than the value of the specific gravity of solids.

Themassspecificgravityisalsoknownastheapparentspecificgravityorthebulkspe cificgravity.

### (2) **AbsoluteSpecificGravity**(**G**<sub>a</sub>):-Thesoilsolidsare

notperfectsolidsbutcontain voids. Some of these voids are permeable through which water canenter, whereas others are impermeable. Since the permeable voids get filledwhen the soil is wet, these are in reality a part of void space in the total massand not apart of soil solids. If both the permeable and impermeable voids are excluded from the volume of solids, the remaining volume is the true or absolute volume of the solids.

The mass density of the absolute solids is used for the determination of the absolute specific gravity of solids.

**VOIDS RATIO**: - It is defined as the ratio of the volume of voids to the volume of solids.

$$e = \frac{VV}{Vs}$$

The void ratio is expressed as a decimal, such as 0.4,0.5, etc. For coarse-grained soils, the void ratio is generally smaller than that for fine-grained soils. For some soils, void ratio may have a value even greater than unity.

**POROSITY**:-Itisdefinedastheratioofthevolumeofvoidstothetotalvolume.

$$n = \frac{Vv}{V}$$

The Porosity is generally expressed as percentage. However, in equations, it is used as a ratio. For example; a porosity of 50% will be used as 0.5 in equations. The porosity of a soil cannot exceed 100% as it would mean Vv is greater than V, which is absurd. Porosity is also known as percentage voids.

Bothporosityandvoidratioaremeasuresofthedenseness(orlooseness)ofsoils. As the soil becomes more and more dense, their values decrease. The term porosity is more commonly used in other disciplines such as agricultural engineering. In soilengineering, the term void ratio is more popular. It is more convenient to use voidratio than porosity. When the volume of a soil mass changes, only the numerator(i.e.Vv) in the void ratio changes and the denominator (i.e.Vs) remains constant. However, if the term porosity is used, both the numeration and the denominator change and it become inconvenient.

Relationshipbetweenthevoidratioandtheporosityasunder.

$$\frac{1}{v} = \frac{v}{v} = \frac{v + vs}{v}$$

$$\frac{1}{1} = 1 + \frac{1}{e} = \frac{1+e}{e}$$

$$n = \frac{1}{e_1}$$

$$\frac{1}{e} = \frac{1}{n} - 1 = \frac{1}{nn}$$

$$e=n_1-n$$
 (2)

Theporosityshouldbeexpressedasaratio(andnotpercentage).

### PERCENTAGEOFAIRVOIDS(na):-

Itistheratioofthevolumeofairtothetotalvolume.

$$n_a = \frac{Va}{V}$$

Itisrepresentedasapercentage.

AIRCONTENT(ac):-

Aircontentisdefinedastheratioofthevolumeofairtot

hevolumeofvoids. Er. ROJALI PATRA DEPT. OF CIVIL GSE, BERHAMPUR

The Aircontentisus ually expressed as a percentage. Both aircontent and the percentage air voids are z erowhen the soil is saturated  $(V_a=0)$ .

Relations hip between the percentage air voids and the air content can be obtained.

$$n_a = \frac{Va}{V} = \frac{Va}{Vv} \frac{Vv}{V}$$

n<sub>a</sub>=nxac

### DegreeofSaturation(S)-

 $\label{thm:continuous} The degree of saturation (S) is the ratio of the volume of water to the volume of voids. It is also represents as S_r.$ 

$$S = \frac{V_W}{V_W}$$

Thedegreeofsaturationisgenerallyexpressedasapercentage.

It is equal to zero when the soil is absolutely dry and 100% when the soil isfully saturated. Degree of saturation is used as a decimal in expressions.

### **DENSITYINDEX:-**

Itthemostimportantindexpropertyofacohesionlesssoil.

It is also known as Density Index  $(I_D)$ .It is also known as relative density ordegree of density. It is used to express the relative compactness of a natural soildeposit.

It is the ratio of the difference between voids ratio of the soil in its loosest stateand its natural voids ratio to the difference between voids ratio in the loosest anddensest states.

$$I_{D}$$
or $Dr = \frac{\text{emax-e}}{\text{emax-emin}} \times 100$ 

n.

$$Dr = \frac{emax - e}{emax - emin} x100$$

Er. ROJALI PATRA DEPT. OF CIVIL GSE, BERHAMPUR

$$Dr = \gamma_d = \frac{\frac{Gywym}{in-1}}{\frac{7v}{1+7s}} = \frac{Gyw}{e} + \frac{Gyw}{e}$$

$$\gamma_d = \frac{Gyw}{e}$$

 $e_{max} The relative density of a soil gives a more clear idea of the dense ness than does the void ratio. \\$ 

### **BULKUNITWEIGHTY:-**

The bulk unit weight is defined as the total weight per total volume.  $\frac{V}{L}$  It is also known as total unit weight ( $\gamma_t$ ) or we tunit weight. In SI unit si tis express as N/mm³ or KN/mm³

### **DRYUNITWEIGHT:-**

Thedryunitweightisdefinedastheweightofsolidspertotalvolume.

$$\gamma_d = \frac{vvs}{v}$$

### **SATURATEDUNITWEIGHT:-**

The saturated unit weight is the bulk unit weight when the soil is fully saturated.

$$\gamma_{\text{sat}} = V$$

### SUBMERGEDUNITWEIGHT:-

Whenthesoilexistsbelowwaterthanitiscalled

submergedcondition.

The submerged unit weight  $(\gamma')$  of the soil is defined as the submerged weight pertotal volume.

$$\gamma_{\text{sub}} = \frac{\text{Wsub}}{\text{V}}$$

### Relationbetween G, S, e, $\gamma \& \gamma_w$ :

 $Equation (1) gives the specific {\color{red} gravity} of solids at the temperature at which the test was conducted.}$ 

 $Specific gravity of solids is generally reported at 27°C or at 4°C. The specific gravity at 27°C and 4°C can be determined from the following equation specific gravity of water at t°C G_{27}=G_1\times$ 

 $G_{27}\!\!=\!\!G_{
m t}\mathsf{X}$ specificgravityofwater at $27^\circ\mathrm{C}$ 

 $And G_4 = G_t \times specific gravity of water at t^{\circ} CWhere G_{27} = specific gravity of particles at 27^{\circ} CG_4 = specific gravity of particles at 4^{\circ} C$   $G_t = specific gravity of particles at t^{\circ} C$ 

### PARTICLESIZEDISTRIBUTION:

- Thepercentageofvarioussizesofparticleinagivendrysoilsampleisfoundbya particlesizeanalysisormechanicalanalysis.
- Mechanicalanalysismeansseparationofasoilintoitsdifferentsizefractio
- Themechanical analysis is performed in two stages
  - (i) Sieveanalysis
  - (ii) Sedimentationanalysisorwetmechanicalanalysis
- The first stage is meant for coarse grained soil only while the secondstage is performed for fine grained soils.
- In general a soil sample may contain both coarse grained particles aswell as fine Particles and hence both the stages of the mechanical analysis may be necessary.

### **SieveAnalysis:**

- In the Indian standard the sieves are designated by the size of theaperatureinmm.
- Thesieveanalysiscanbedividedintotwopartsi.ethecoarseanalysisandfin eanalysis.
- Anovendriedsampleofsoilisseparatedintotwofractionsbysievingitthrou gha4.75mmI.Ssieve.
- The portion retained on it is termed as the gravel fraction and is keptfor the coarse analysis while the portion passing through it is subjected to fine sieve analysis.
- The following sets of sieves are used for coarse sieve analysis: IS: 100.63,20,10and4.75mm.
- The sieves used for fine sieve analysis are: IS: 2 mm, 1.0 mm, 600,425,300, 212,150 and 75 micron.
- Sieving is performed by arranging the various sieves one over the other in the order of their mesh openings the largest aperature sieve beingkeptatthetopandthes mallest aperature sieve at the bottom.
- Areceiveriskeptatthebottomandacoveriskeptatthetopof wholeassembly.
- Thesoilsampleisputonthetopsieveandthewholeassemblyisfittedonasiev eshakingmachine.
- The amount of shaking depends upon the shape and the number ofparticles.
- Atleast10minutesofshakingisdesirableforsoilswithsmallparticles.
- Theportionofthesoilsampleretainedoneachsieveisweighed.
- Thepercentageofsoilretainedoneachsieveiscalculatedonthebasisofthet otalmassofsoilsampletakenandfromthispercentagepassingthrougheach sieve iscalculated.

## SedimentationAnalysis:

- In the wetmechanical analysisor sedimentation analysis the soilfraction finer than 75 micron size is kept in suspension in a liquid(usuallywater)medium.
- Theanalysisisbasedonstokeslawaccordingtowhichthevelocityatwhich grains settle out of suspension, all other factors being equal, isdependentupontheshape, weight and size of the grain.
- However in the usual analysis it is assumed that the soil particles are spherical and have the same specific gravity.
- Withthisassumptionthecoarserparticlessettlemore quicklythanthefinerones.

• If vistheterminal velocity of sinking of a spherical particle it is given by

$$v = \frac{2r^{2}\gamma_{s} - \gamma_{w}}{9}$$

$$Orv = \frac{1D}{18}$$

Wherer=radiusofthesphericalparticle(m)D=di

ameterofthesphericalparticle(m)

v=terminalvelocity(m/sec)

γ<sub>s</sub>=unitweightofparticles(KN/m<sup>3</sup>)

γ<sub>w</sub>=unitweightofliquidorwater(KN/m<sup>3</sup>)

 $=H_e/6000tm/sec$ 

# Substituting in the above equation we get $D=\sqrt{}$

$$\begin{array}{c} 18\times10^{6}\overline{\eta H_{e}} \\ = \sqrt{\frac{(G-1)\gamma_{w}\times6000t}{\sqrt{\frac{e}{C}}}} \\ = \sqrt{\frac{3000\eta \ H}{\sqrt{\frac{e}{C}}}} \\ (G-1)\gamma_{w} \ t \\ D = 10^{-5}F\sqrt{\frac{H}{e}} \\ t \\ Where F = 10^{5}\sqrt{\frac{3000\eta}{(G-1)\gamma_{w}}} is a constant factor for given values of  $\eta$  and  $G$ .$$

 $At 27^{\circ}C, the viscosity \mu of the distilled water is approximately 0.00855 poise. Since 1 poise is equivalent to 10^{-4} kN-s/m^2$ 

Wehave==0.00855×10-4KN-

s/m<sup>2</sup>TakinganaveragevalueofG=2.68

Puttingthese value in v= $\frac{D^{2}(9.81)(2.68-1)}{D^{2}(9.81)(2.68-1)}$ We get v= $\frac{D^{2}(9.81)(2.68-1)}{18 \times 10^{6} \times 0.0085 \times 10^{-4}}$ =1.077 D<sup>2</sup>(m/sec)

This is an approximate version of Stoke's law and can be easily remembered for roughdetermination.

- The sedimentation analysis is done either with the help of hydrometerorapipette.
- Inboththemethods asuitableamountof ovendriedsoilsample,finerthan75micronsizeismixedwithagivenvolumeV ofdistilledwater.
- Themixtureisshakenthoroughlyandthetestisstartedbykeepingthejarcon tainingsoilwatermixture, vertical.
- Atthecommencementofsedimentationtestsoilparticlesareassumedtobe uniformlydistributedthroughoutthesuspension.
- Afteranytimeintervalt,ifasampleofsoilsuspensionistakenfromaheight
   H<sub>e</sub>(measured from the top level of suspension), only thoseparticles
   will remain in the suspension which have not settled duringthis
   timeinterval.

The diameter of those particles which are finer than those which have already settled can be found from D=10 -5 F  $\sqrt{\frac{H_e}{t}}$   $\frac{-}{t}$ 

- The greater the time interval t allowed for suspension to settle, the fineraretheparticlessizes retained at this depth H<sub>e</sub>.
- $\bullet \quad Hence sampling at different time intervals, at this sampling depth H_e \\ would give the content of particles of different sizes.$
- ullet Ifatanytimeintervalt,  $M_D$  is the mass, perml, of all particless maller than the diameter D still in suspension at the depth  $H_e$  the percentage finer than D is given by

 $Where N \!\!=\!\! percentage finer than the diameter D$ DEPT. OF CIVIL GSE, BERHAMPUR Er. ROJALI PATRA

 $M_d$ =totaldrymassofallparticlesputinthesuspensionV=volume of suspension

Thus with the help of above equations we can get various diameter D and the percentage of particles finer (N%) than this diameter.

## Limitationofsedimentationanalysis:

- (1) The sedimentation analysis gives the particle size in terms of equivalentdiameter, which is less than the particle size given sieve analysis. The soil particles are not spherical. The equivalent diameter is close to the thickness (smallest dimension) rather than the length or width.
- (2) As the specific gravity of solids for different particles is different, the use of an average value of G is a source of error. However as the variation of the values of G is small the error is negligible.
- (3) Stokes law is applicable only when the liquid is infinite. The presence ofwallsofthejaraffectstheresulttosomeextent.
- (4) In stokes law it has been assumed that only one sphere settle and there isno interface from other spheres. In the sedimentation analysis as manyparticlessettlesimultaneouslythereissomeinterface.
- (5) Thesedimentationanalysiscannotbeusedforparticleslargerthan 0.2 mmasturbul entconditions develop and stokes law is not applicable.
- (6) The sedimentation method is not applicable for particles smaller than 0.2μbecauseBrownianmovementtakesplaceandtheparticlesdonotasperStokesl aw.

# PIPETTEMETHOD:

- Thepipettemethodisthestandardsedimentationmethodusedinthelaborat ory.
- The equipment consists of a pipette, a jaranda number of sampling bottles.
- Generallyaboilingtubeof500mlcapacityisusedinplaceofajar.

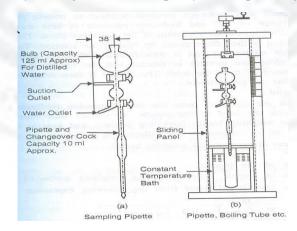

Figure 3.4

- The figure shows a pipette for extracting samples from the jar from adesireddepth(H<sub>e</sub>).
- The pipette consists of a 125 ml bulb with stop cock for keepingdistilledwater, athreeways topcock, suction and wastewater outlet s, sampling pipette of 10 mlcapacity.
- The method consists in drawing off samples of soil suspension, 10 mlin volume, by means of this pipette from a depth of 10 cm (H<sub>e</sub>) atvarioustimeintervalsafterthecommencementofthesedimentation.
- The recommended time intervals are: ½, 1, 2, 4, 8, 15 and 30 minutes and 1, 2, 4, 8, 16 and 24 hours reckoned from the commencement of the test.
- The pipette should be inserted in the boiling tube about 25 secondsbefore the selected time interval and the time taken for sucking thesampleshouldnotbemorethan 10 to 20 seconds.
- Each sample so taken is transferred into suitable sampling bottles and driedinanoven.
- The mass M<sub>D</sub>of solids per ml of suspension is thus found by takingthedrymass and dividing it by 10.

# **Methodofpreparingsoilsuspension:**

- Inthesedimentationanalysisonlythose particleswhicharefinerthan75micronsizeareincluded.
- About 12 to 30 gm of oven dried sample is accurately weighed andmixed with distilled water in a dish or beaker to form a smooth thinpaste. To have proper dispersion of soil a dispersing agent is added to the soil. Some of the common dispersing agents are sodium oxalate, sodium silicate and sodium polyphosphate compounds such as
  - tetraso dium pyrophos phate, so dium hexameta phosphate and so dium tripolyphosphate.
- IS 2720 recommends the use of dispersing solution containing 33 gmof the sodium hexametaphosphate and 7 g of sodium carbonate indistilledwatertomakeone litreof solution.
- 25 ml of this solution is added to the dish (containing the soil and distilled water) and the mixture is warmed gently for about 10 minutes.
- The contents are then transferred to the cup of a mechanical mixer, using a jet of distilled water to wash all traces of the soil out of the evaporating dish.
- Thesoilsuspensionisthenstirredwellfor15minutes.
- The suspension is then washed through 75 micron IS sieve, using jet ofdistilledwaterandthesuspension, which has passed through the sieve, is transferred to the 500 mlcapacity boiling tube (sedimentation tube).

The tube is then filled to the 500 ml mark by adding distilled water.GSE, BERHÅMPUR DEPT. OF CIVIL Er. ROJALI PATRA

- Thetubeisthenputinaconstanttemperaturewaterbath.
- Whenthetemperature is then tube has been stabilised to the temperature of the bath, the soil suspension is thoroughly shaken by inverting the tubes ever altimes, and then replaced in the bath.
- Thestopwasthenstarted and the soils amples are collected at various time intervals with the help of pipette.

#### Calculation of DandN:

- 10 ml samples are collected from the soil suspension (sedimentationtube)fromadepthof10cm,withthehelpofthepipetteatvari oustimeintervals.
- The samples are collected into the weighing bottles (sampling bottles) and keptin the oven for drying.
- The mass  $M_D$ , per ml of suspension so collected is calculated as under  $:M_D=$ drymassofsampleintheweighing bottle/ $V_P$

Where V<sub>P</sub>=volume of the pipette

= volume of sample collected in the weighing bottle = 10 mlThepercentagefineriscalculated fromthefollowingexpression

$$N' = \frac{\stackrel{M}{\longrightarrow} 100}{\stackrel{MD}{\longrightarrow}}$$

 $Where \verb|m==| mass of dispersing agent present in the in the total suspension of volume V$ 

V=volumeofsuspension=500mlN'=p

ercentagefinerbasedonM<sub>D</sub>

### **HYDROMETERMETHOD:**

- The hydrometer method of sedimentation analysis differs from the pipetteanalysis in the method of taking observation.
- In the pipette analysis the mass M<sub>D</sub>per ml of suspension is founddirectly by collecting a 10 ml sample of soil suspension from thesamplingdepthH<sub>e</sub>.HoweverinthehydrometeranalysisM<sub>D</sub>iscomputed indirectly by reading the density of the soil suspension at adepthH<sub>e</sub>atvarioustime intervals.
- In the pipette test the sampling depth  $H_e$  is kept constant while in thehydrometer test, the sampling depth  $H_e$ goes on increasing as the particles settle with the increase in the time interval. It is thereforenecessary to calibrate the hydrometer.

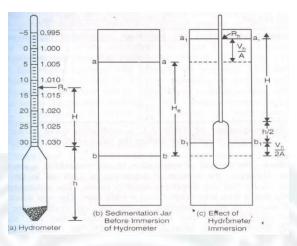

Figure 3.5

### Calibrationofhydrometer:

- The readings on the hydrometer stem give the density of the soilsuspensionsituated at the centre of the bulbatany time.
- Forconvenience, the hydrometer readings are recorded after subtracting 1 and multiplying the remaining digits by 1000. Such a reduced reading is designated as R<sub>h</sub>.
- For example, if the density reading at the intersection of horizontalsurfaceofsoilsuspensionwith thestemis1.010,itisrecordedas10 i.eR<sub>h</sub>=10.
- As indicated in figure the hydrometer reading R<sub>h</sub>is increase in thedownwarddirectiontowardsthehydrometerbulb.
- LetHbetheheightincmbetweenanyhydrometerreadingRhandtheneck,a ndhtheheightofthebulb.
- Figure(b)showsthejarcontainingthesoilsuspension.
- When the hydrometer is immersed in the jar as shown in figure (c) thewater level as rises to a<sub>1</sub>a<sub>1</sub>, the rise being equal to the volume V<sub>h</sub> of the hydrometer divided by the internal area of cross section A of thejar.
- Similarly the level bb rises to b<sub>1</sub>b<sub>1</sub>, where bb is the level situated at adepth H<sub>e</sub>below the top level aa, at which the density measurements ofthesoilsuspensionarebeingtaken.
- Therisebetweenbbandb<sub>1</sub>b<sub>1</sub>willbeapproximatelyequaltoV<sub>h</sub>/2A.
- Thelevelb1b1isnowcorrespondingtothecentreofthebulb,butthesoilpart iclesatb1b1areofthesameconcentrationastheywereatbb.

haveH=
$$(H+^h+^V_h)$$
-Vh
e
2 2Æ Æ
=H + $^1$ /2(h- $^V_h$ )

- Intheabove expression therearetwovariables:theeffectivedepthHeandthedepthHwhichdepends upon thehydrometerreading  $R_h$ .
- Therefore by selecting various hydrometer reading R<sub>h</sub>, the depth H canbe measured with the help of an accurate scale and the correspondingdepthH<sub>e</sub>canbefound.
- Theheighthofthebulbisconstant.SimilarlyV<sub>h</sub>andAareconstant.
- To find the volume of the hydrometer it is weighed accurately. Themassofthehydrometeringramsgivethevolumeofthehydrometerinmi llilitres.

### **Testprocedure:**

- The methodofpreparationofsoilsuspensionis thesameas indicated in the pipettetest.
- Howeverthevolumeofsuspensionis 1000 mlinthis case and hencedoubles the quantity of drysoil and dispersing agentistaken.
- Thesedimentationjarisshakenvigorouslyandisthenkeptverticaloverasol idbase.
- Thestopwatchisstartedsimultaneously.
- Thehydrometerisslowlyinsertedinthejarandreadingsaretakenat ½,1and2minutestimeinterval.Thehydrometeristhentakenout.
- More readings are then taken at the following time intervals: 4, 8, 15,30minutesand1,2,4hoursetc.
- To take the reading, the hydrometer is inserted about 30 seconds beforethegiventimeinterval, so that it is stable at the time when the reading is to be taken.
- Sincethesoilsuspensionisopaquethereadingistakencorrespondingtothe upperlevelofthemeniscus.

### **Correctiontothehydrometerreading:**

Thehydrometerreadingsarecorrected as under:

### (i) Meniscuscorrection:

- Sincethesuspensionisopaque, the observations are taken at the top of theme niscus.
- Themeniscuscorrectionisequaltothereadingbetweenthetopofthemeniscusandthelevelofthesuspension.
- As the marking on the stem increase downward the correction ispositive.
- The meniscus correction (C<sub>m</sub>) is determined from the readings at thetopandbottomofmeniscusinthecomparisoncylinder. Themeniscusco rrectionisconstantforahydrometer.
- If R<sub>h</sub>' is the hydrometer reading of the suspension at a particular

 $time, the corrected hydrometer R_h reading is given by \\$  $R_h=R_h'+C_m$ GSE, BERHÅMPUR DEPT. OF CIVIL Er. ROJALI PATRA

### (ii) Temperaturecorrection:

- The hydrometer is generally calibrated at 27°C. If the temperature of the suspension is different from 27°C a temperature correction (C<sub>t</sub>) is required for the hydrometer reading.
- If the temperature is more than 27°C, the suspension is lighter and theactualreadingwillbelessthanthecorrectedreading. The temperature correction is positive.
- Ontheotherhand, if the temperature is less than 27°C the temperature correction is negative.

# (iii) Dispersionagentcorrection:

- Addition of the dispersing agent to the soil suspension causes anincreaseinthespecificgravityofthesuspension.
- Thereforethedispersingagentcorrectionisalwaysnegative.
- The dispersing agent correction (C<sub>d</sub>) can be determined by noting thehydrometer reading in clear water and again in the same water afteraddingthedispersingagent.
- Thus the corrected reading Rcan beobtained from the observed reading R<sub>h</sub>'asunder

 $R=R_h'+C_m\pm C_t-C_d$ 

### (iv) CompositeCorrection:

- Insteadoffindingthecorrectionindividually, it is convenient to find one composite correction.
- The composite correction (C) is the algebraic sum of all the correction. Thus R=

 $R_h' \pm C$ 

• The composite correction is found directly from the readings taken in acomparisoncylinder, which has distilled water and the dispersing agent in the same concentration and has the same temperature.

# **ComputationofDandN:**

 $\bullet \quad The particle size Discalculated from the following formula D=10^{\circ} \\$ 

 ${}^{5}\text{F}\sqrt{\frac{\text{H}}{}}$ 

t

- To compute the percentage of the soil finer than this diameter, the massM<sub>D</sub>per ml of suspension at effective depth H<sub>e</sub>is first computed asunder
- Since the hydrometer readings have been recorded by subtracting 1fromthedensity(b)readingsandmultiplyingthemby1000,wehave

Er. ROJALI PATRA

DEPT. OF CIVIL

GSE, BERHAMPUR

$$Or,b=1+R/1000$$
\_\_\_\_\_(i)

Where b is the density reading actually marked on the hydrometer and R is thehydrometerreading corrected for the composite correction.

• Now let us consider 1 ml of soil suspension at a time interval t at the effective depth  $H_e$ . If  $M_D$  is the mass of solids in this 1 ml suspension them ass of waterinit will be

 $1-M_D/G$ 

Totalmassof1mlsuspension
$$\exists -\underline{M}^{\underline{D}}$$
 +M<sub>D</sub>

Hencedensity of the suspension = 
$$1 - \frac{M_D}{G} + M_D$$
 (ii)

Equatingequation(i)and(ii)weget

$$1+R/1000 = \underbrace{M_{DG} + M}_{1-}$$

$$M_D = \frac{R (G)}{1000G-1}$$

WhereG=specificgravityofsoilsolids

SubstitutingthesevaluesinequationN=MD×100

$$M_{\rm D/7}$$

WegetN'= 
$$\frac{\frac{R(G)}{1000G-1} \times 100}{Md/V}$$

 $\begin{array}{c} TakingV = 1000 ml we get \\ 100 GR \end{array}$ 

$$N' = Md(G-1)$$

WhereN'=percentagefinerwithrespecttoM<sub>d</sub>

ThusforvariousvaluesofR, N'canbecalculated

 For a combined sieve and sedimentation analysis if M is the total drymass of soil originally taken (before sieving it over 2mm sieve) theoverallpercentagefinerNis givenby

$$N=N'\times^{M'}$$

WhereM'=cumulativemasspassing2mmsieveM=tot

aldrymassofsoilsample

If the soils ample does not contain particles coarser than 2 mm size, N and N' will be equal.

#### **CONSISTENCYOFSOIL:**

- Consistencymeanstherelativeeasewithwhichsoilcanbedeformed.
- Consistencydenotesdegreeoffirmnessofthesoilwhichmaybetermedass oft,firm,stifforhard.
- Finegrainedsoilmaybemixedwithwatertoformaplasticpastewhichcanb emouldedintoanyform bypressure.
- Theadditionofwaterreducesthecohesionmakingthesoilstilleasier

tomould.

- Ifwaterisevaporatedfromsuchasoilsuspensionthesoilpassesthroughvari ousstages orstatesofconsistency.
- SwedishagriculturistAtterbergdividedtheentirerangefromliquidtosolid state intofourstages:
  - (i) Liquidstate
  - (ii) Plasticstate
  - (iii) Semi-solidstate
  - (iv) Solidstate

He sets arbitrary limits known as consistency limit or Atterberg limit for the sedivisions in terms of water content

- Thusconsistencylimitsarethewatercontentatwhichthesoilmasspassesfr omonestatetothe next.
- The Atterberg limits which are most useful are:
  - (i) Liquidlimit
  - (ii) Plasticlimit
  - (iii) Shrinkagelimit

**Figure** 

#### 3.6Differentstatesofso

# LiquidLimit:

il

- Liquid limit is the water content corresponding to the arbitrary limitbetweenliquidandplastic stateofconsistencyofasoil.
- It is defined as the minimum water content at which the soil is still intheliquidstatebuthasasmallshearingstrengthagainstflowingwhichcan bemeasuredbystandardavailablemeans.

Er. ROJALI PATRA

DEPT. OF CIVIL

GSE, BERHAMPUR

• With reference to the standard liquid limit device, it is defined as theminimum water content at which a part of soil cut by a groove ofstandard dimension, will flow together for a distance of 12 mm underanimpactof25blowsinthedevice.

#### **Plasticlimit:**

- Plastic limit is the water content corresponding to an arbitrary limitbetweentheplasticandthesemi-solidstateofconsistencyofasoil.
- It is defined as the minimum water content at which a soil will justbegin to crumble when rolled into a thread approximately 3 mm indiameter.

# **Shrinkagelimit:**

- Shrinkage limit is defined as the maximum water content at which areductioninwatercontentwillnotcauseadecreaseinthevolumeofasoilm
- It is lowest water content at which a soil can still be completely saturated.

# PlasticityIndex:

- Therangeofconsistencywithinwhichasoilexhibitplasticpropertiesiscall edplasticrangeandisindicated by plasticity index.
- Plasticityindex is defined is defined asthe numerical differencebetweentheliquidlimitandtheplasticlimitofasoil.

 $I_p = w_l - w_p$ 

- Whenplasticlimitcannotbedetermined,theplasticityindexisreportedas NP(Nonplastic).
- Whentheplasticlimitisequaltoorgreaterthantheliquidlimittheplasticityi ndexisreported aszero.

# **Plasticity:**

• Plasticity is defined as that property of a soil which allows it to be deformed rapidly, without rupture, without elastic rebound and without volume change.

## **ConsistencyIndex:**

• The consistency indexor the relative consistency is defined asthe ratioof the liquid limit minus the natural water content to the plasticityindexofsoil

$$I_{\overline{c}}^{\underline{w_{l-w}}}$$

Wherewisthenaturalwatercontentofthesoil

- If consistency index of a soil is equal to unity, it is at the plastic limit.
- SimilarlyasoilwithIcequaltozeroisatitsliquidlimit.

 $If I_c exceeds unity the soil is in a semi-solid state and will be stiff. \\$ Er. ROJALI PATRA DEPT. OF CIVIL GSE, BERHAMPUR  A negative consistency index indicates that the soil has natural watercontent greater than the liquid limit and hence behaves just like aliquid.

# Liquidityindex:

Theliquidityindexorwater
 plasticityratioistheratio,expressedasapercentage,ofthenaturalwatercon
 tentofasoilminusitsplasticlimittoitsplasticity index:

$$I = \frac{w - w_p}{1 - w_p}$$

Wherewisthenaturalwatercontentofthesoil.

# Example-1

- Duringatestforwatercontentdeterminationonasoilsamplebypycnomete r,thefollowing observations weretaken
  - (1) Massofwetsoilsample =10
  - (2) Massofpycnometerwithsoilandfilledwithwater =2000gm
  - (3) Massofpycnometerfilledwithwateronly=1480gm
  - (4) Specificgravityofsolids

=2.67Determine

thewatercontent.

## **Solution:**

Weknowthatw=[
$$(\frac{M2-M1}{M3-M4})(\frac{G-}{1G})-1]\times 100$$

=
$$\left[\frac{1000}{(2000-1480)}\times\left(\frac{2.67-1}{2.67}\right)-1\right]\times100$$

$$=20.28\%$$

Hencewatercontentofthesampleis 20.28%.

(Ans)

# Example2:

The mass of an empty gas jar was 0.498 Kg. When completely filled with water itsmass was 1.528 Kg. An oven dried sample of soil mass 0.198 Kg was placed in the jarandwater wasaddedtofillthejaranditsmasswasfoundtobe 1.653Kg. Determinethespecificgravityofparticle.

**Solution:** we know

that<sub>G=
$$^{M_{2-M_{1}}}$$</sub>  $(M_{2-M_{1}})-(M_{3-M_{4}})$ 

$$=2.71$$

Hencespecificgravityofthesampleis 2.71.

# Example3:

A soil sample consisting of particles of size ranging from 0.5 mm to 0.01 mm, is putonthesurfaceofstillwatertank5metresdeep.Calculatethetimeofsettlementofthecoars est and the finest particle of the sample, to the bottom of the tank. Assumeaveragespecificgravityofsoilparticlesas2.66andviscosityofwateras0.01poise.

#### **Solution:**

$$v = \frac{D^{2}\gamma_{w}(G-1)}{18\times10^{6}\eta}$$
$$= \frac{D^{2}(G-1)}{1.835\times10^{6}\times\eta}$$

HereG=2.66and $\mu$ = $0.01 \times 10^{-4}$ = $10^{-6}$ KN-s/m<sup>2</sup>

$$v = \frac{D^2}{1.835} \frac{2.66-1}{10^6(10^{-6})}$$
$$= 0.905D^2$$

Wherevisinm/secandDisinmmFor

coarsest particle D = 0.5

$$t = h/v = 5/0.2263 = 22.1$$

secondsforthefinestparticle,D=0.01

$$mmv=0.905(0.01)^2=9.05\times10^{-5}m/sec$$

$$t = \frac{5}{9.05 \times 10^{-5}} = 55249 \text{sec} = 15 \text{hours} = 20 \text{min} = 49 \text{sec}$$

## **Example4:**

50gramsofovendriedsoilsampleistakenforsedimentationanalysis. Thehydrometer reading in a 100 ml soil suspension 30 minutes after the commencement of sedimentation test is 24.5. The effective depth for  $R_h$ = 25, found from the calibration curve is 10.7 cm. The meniscus correction is found to be +0.5 and the composite correction as – 2.50 at the test temperature of 30°C. Taking the specific gravity of particles as 2.75 and viscosity of water as 0.008 poise, calculate the smallest particle size which would have settled during this interval of 30 minutes and the percentage of particles finer than this size.

## **Solution:**

$$R_{h}'=24.5$$

$$R_h = 24.5 + 0.5 = 25$$

$$D = \sqrt{\frac{3000\eta}{(G-1)\gamma_w}} \sqrt{\frac{H_e}{t}}$$

Where Disinmm, Heisincmandtisinminute. Here II=

 $0.008 \times 10^{-4} \text{KN-s/m}^2$ 

$$G=2.75$$
and $\gamma_w=9.81$ KN/m $^3$ t=3

0min.

$$D = \sqrt{\frac{3000 \times 0.008 \times 10^{-4}}{(2.75 - 1)9.81}} \sqrt{\frac{10}{30}}$$

 $=7.06\times10^{-3}$ mm

=0.00706mm

The percentage fineris given by N'=

 $Where M_d = mass of drysoil = 50 gm$ 

$$N' = \frac{100 \times 2.75}{50(2.75 - 1)} \times 22$$

(Ans)

# **Example5:**

A soil has a liquid limit of 25 % and plastic limit is 15 %. Determine the plasticityindex.Ifthe

water content of the soil in its natural condition in the field is 20%, find the liquidity index and relative consistency.

## **Solution:**

$$w_1 = 25\%$$

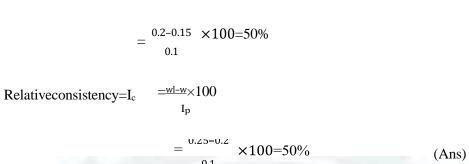

$$w_p = 15\%$$

$$w=20\%$$

 $plasticityIndexI_p\!\!=\!\!w_l\!\!-\!\!w_p$ 

$$Liquidity index=I= \stackrel{w-w_p}{\underset{I_p}{=}} \times 100$$

Er. ROJALI PATRA DEPT. OF CIVIL GSE, BERHAMPUR

#### **CHAPTER-4**

# **CLASSIFICATIONOFSOIL**

Purposeofsoilclassification:

The purpose of soil classification is to arrange various types of soil into specific groupsbased on physical properties and engineering behavior of the soils with the objective offindingthesuitabilityofsoilsfordifferentengineeringapplication, such as in the construction of earthdams, highway, and found at ions of building, etc.

For different areas of applications and withthe need for simplicity and acceptable terminology, several soil classification system s have been developed over theyears, three of which are listed below.

- 1. Highwayresearchboardclassificationsystem
- 2. Unifiedsoilclassificationsystem
- 3. Indianstandardsoilclassification.

HighwayResearchBoard (HRB)classificationSystem:

The Highway Reach Board classification system, also known as Revised Public RoadsAdministration classification system, is used to find the suitability of a soil, as sub gradematerial in pavement construction. This classification system is based on both particle sizerangesand plasticity characteristic soilare divided into 7 primary group designated as A -1,A-2.......A-7,asshownintable 4.1.

Group A-1, is divided into two sub groups A-1 and A-1 and group A-2into four subgroups, A-2-4, A-2-5, A-2-6 and A-2-7. A characteristic group index is used to describe the performance of a subgrade material.

Groundindexisnotused to place a soil in a particular group; it is actually a means of rating the value of soil as a sub grade material within its own group . The higher the value of the group index, the proper is the quality of the material.

The group index of a soil depends upon.

- (i) Amountofmaterialpassingthe75-micronsieve,
- (ii) Liquidlimit
- (iii) Plasticlimit

Groupindexisgivenbythefollowingequation:

Group

index=0.2a+0.005ac+0.01bdWhere

 $a = that\ portion of percentage passing 75 micronsie vegreater$ 

than35andnot exceeding 75expressedaswholenumber(0 to40)

b=that portion percentagepassing 75micron sievegreater than 15

andnotexceeding55expressedaswholenumber(0 to 40)

c=thatportionof thenumericalliquid limit greaterthan

40andnotexceeded60expressedasapositivewholenumber(0to 20)

d=that portion of the numerical plasticity in dex greater than 10 and not exceeding 30 expressed as a positive whole number (0 to 20).

To classify a given soil, sieve analysis data, liquid limit and plasticity index are obtained andwe proceed from left to right in the Table 4.1 and by Process of elimination find the firstgroupfromintowhichthetestdatawillfit. This gives the correct Classification. The plasticity index of A-7-5 subgroup is equal to or less than liquid limit minus 30. The plasticity index of A-7-6 subgroup is greater than liquid limit minus 30.

Note: The PRA system was introduced in 1928 and revised in 1945 as HRB system. It isknown as AASHTO system since 1978 after adoption by American Association of StateHighwayandTransportation Officials.

## Unifiedsoil classificationSystem

The Unified soil classification system is based on the Airfield Classification system that wasdevelopedbyACasagrande.thesystembasedonbothgrainsizeandplasticitycharacteristicof soil. The unified Soil classification (USC)system was adopted jointly by theCorpsofEngineers,U.S.armyandU.S.BureauofReclamationduring1950s.

# <u>INDIANSTANDARDSOILCLASSIFICATIONSYSTEM</u>

Indian standard soil classification system (IS 1498-1970 classification andidentification of soil for general engineering purpose) is esssentially based onunified soil classification system and the salient features and given in thefollowing discussion.

Inthesystemsoilsarebroadly dividedinto3division

- 1. coarse- grained soil –if more than 50% by mass is retain on 75 micron ISsieve.
- 2. Finegrainedsoil-ifmorethan50%bymasspassesthrough75micronlSsieve.
- 3. Highlyorganicsoilsandothermiscelliounssoilmaterial. The soil content larger % of fibrous organic matter such as peat and particles of decompose vegetation. In additions hortensoil containing shells, concretions cinders and other non soil material insufficient quantities are also

group edin this division. Coarse grained so ils are grouped as gravels and sands with group symbols Gand S

Gravels(G)ifmorethan50%bymassofthecoarsegrainedfractionpassedthroug h4.75mmlSsieve.

Depending on the gradation gravels(G) and sands (S) are further described usinggroupsymbolsareindicatedbelow.

GW-Well graded gravel for which Cu>4 and Cclies between 1&3

GP-poorlygradedgravelwhichdoesnotmeetallgraduationrequirement

of

**GW** 

SW-WellgradedsandforwhichCu>6andCcliesbetween1&3GM-siltygravelif lp> 4forfine-grainedfraction.

GC-Clayey gravel if Ip < 7 for fine-grained fraction.SM-Siltysandiflp<4forfinegrainedfraction.

SC-Clayeysandiflp>7forfine-grainedfraction.

In the case of coarse –grained soils mixed with fines if Ip lies between 4and 7 one has to use proper judgment in dealing with this border line case.Generally non-plastic classification is favored in such cases. For example asandwith10%fineswithCu>6,Ccbetween1and3andIp=

6wouldbeclassifiedasSW-SMratherthanSW-SC.

Fine-

grainedsoilsaregroupedunderfollowingthreesubdivisionswithrespectivegroupsymbols:

Inorganicsiltsandveryfinesands(M)In

organicclays(C)

Organics ilts, Organic clays and Organic matter (O)

Dependingonliquidlimitwhichisconsideredagoodindexofcompressibilityfinegrain ed soils are described as possessing (i)low compressibility (L) when liquidlimitislessthan35percent.

(ii) in terme diateor medium compressibility (I) when liquid limit lies between 35 percent

(iii)highcompressibility(H)whenliquidlimitisgreaterthan50percent.

The plasticity chart originally devised by A. Casagrande and slightlymodifiedbylSisusedtoclassifyfine-grainedsoilsinthelaboratory.

The A-line having the equation:

lp=0.73(WI-20)

Andthetwoverticallinesatwl=35andwl=50dividethechartintosixregionswithgroup symbols marked as shown in Fig.4.4 if the plotted position lies belowA-line, the soil has to be checked for organic odour by slight heating. Ifnoorganic odour is smelt than only it should be classified as inorganic silt. In case

Er. ROJALI PATRA DEPT. OF CIVIL GSE, BERHÅMPUR

of doubt, the soils hould be oven-dried and its liquid limit determinedEr. ROJALI PATRA DEPT. OF CIVIL GSE, BERHAMPUR again. In the case of organics oils the rewill be larger eduction in liquid limit on drying (reduction generally > 25%).

#### **CHAPTER-5**

# PERMEABILITYANDSEEPAGE

# 5.1 ConceptofPermeability:-

- > Thepropertyofsoilwhichpermitsflowofwater(orotheranyliquid)throughit is called the permeability in otherworld, thepermeabilityinthecase withwhichwatercanflowthroughit.
- > Permeabilityisveryimportantengineeringpropertyofsoil.
- > The knowledge of permeability essentialin a number of soil engineering problems such as: Settlement of Buildings, Yield of wells, Seepage through and below the earth surface.
- Permeabilitycontrolsthehydraulicstabilityofsoilmasses.
- > The permeability of soils is also required in the design of filters required topreventpipinginhydraulicstructure.

## Darcy'sLaw:-

TheflowoffreewaterthroughsoilisgovernedbyDarcy'slaw.In1856,Darcyexperimentally that for laminar flow in a homogeneous soil, the velocity of flow (v) isgivenby

v=ki <u>Equat</u>ion no-1

Where,k=coefficientofpermeability,i=hydraulicgradientandv=velocityofflowinlaminarflowinhomogeneoussoil

TheaboveequationisknownasDarcy'slaw,whichisoneofthecornerstonesofsoilengi neering.Thedischarge'q'isobtainedbymultiplyingthevelocityofflow

(v) bythetotalcross-sectionalarea(A)normaltothedirectionofflow

Thus,q=vA=kiA — Equationno-2

 $Note: -1) The velocity of flow is also known as discharge velocity or superficial velocity. \\ 2) The area Ain the above equation includes both the solids and the voids.$ 

## Co-efficientofPermeability:-

 $\textbf{{\it }} \qquad \text{The coefficient of permeability can be defined using the equation 1. If the hydraulic gradient is unity, the coefficient of permeability is equal to the velocity of flow.}$ 

Or,

- > The coefficient of permeability is defined as the velocity of flow which wouldoccur under unit hydraulic gradient. The co-efficient of permeability isequaltothevelocityofflow.
- ➤ Thecoefficientpermeabilityhasthedimensionsofvelocity[L/T].
- > The coefficient of permeability measured in mm/sec, cm/sec, m/sec, m/dayorothervelocityunits.
- > The coefficient of permeability depends upon the particle size and uponmanyfactors.
- According to USBR, the soil having co-efficient permeability greater than 10<sup>-3</sup>mm/sec are classified as pervious and those with a value less than 10<sup>-5</sup> to 10<sup>-3</sup>mm/secaredesignatedassemi-pervious.

# 5.2 FactorsaffectingPermeabilityofsoils:-

The following factors affect the permeability of soils.

- (1) ParticleSize.
- (2) Structureofsoilmass.
- (3) Shapeofparticles.
- (4) Voidratio.
- (5) Propertiesofwater.
- (6) Degreeofsaturation.
- (7) Adsorbedwater.
- (8) Impurities inwater.
- (1) <u>ParticleSize:-</u>Co-efficient ofpermeabilityofsoilisproportionaltothesquare of particle size (D). The permeability of coarse grained soils is very large ascompared to that of fine-grained soils. The permeability of coarse sand may be more thanonemilliontimesasmuchthatofclay.

#### (2) Structureofsoilmass:-

ThecoefficientCtakesintoaccounttheshapeofflowpassage. The size of flow passage depends upon the structural arrangement. For samevoid ratio, the permeability is more in the case of flocculated structure as compared tothatinthedispersesstructure.

Stratifiedsoildepositshavegreaterpermeabilityparalleltotheplaneofstratification than that perpendicular to this plane. Permeability of soil deposit also depends upon shrinkage cracks, joints, fissures and shear zones. Loess deposits have greater permeability in the vertical direction than in the horizontal direction.

The permeability of natural soil deposit should be determined in undisturbed condition. The disturbance caused during sampling may destroy the original

structure and affect the permeability. The effect of disturbance is more pronounces in case of fine-grained so il sthan in the case of coarse-grained so il s.

(3) <u>Shape of Particles: -</u> The permeability of a soil depends upon the shape of particles. Angular particles have greater specific surface are as compared with the

rounded particles. For the same void ratio, the soils with angular particles are lesspermeablethanthosewithroundedparticles, as the permeability is inversely

proportionaltothespecificsurface. However, in an atural deposit, the void ratio for a soil with angular particles may be greater than that for rounded particles, and the soil with angular particles may be actually more permeable.

<u>(4) Void Ratio:</u> For a given soil, the greater the void ratio, the higher is thevalueofthecoefficientofpermeability.

Basedontheotherconcepts, it has been established that the permeability of soil varies as  $e^2$  Or  $e^2$ / (1+e) (figure-2). Whatever may be the exact relationship; alloil shave ever suslog kplot as a straightline (figure-1).

Figure(1) Figure(2)

Er. ROJALI PATRA DEPT. OF CIVIL GSE, BERHAMPUR

If the permeability of a soil at a void ratio of 0.85 isknown, its value at another void ratio of 'e' can be determined using the following equation given by Casagrande:

#### $k=1.4k_{0.85}e^2$

Where  $k_{0.85}$  = permeability at void ration of 0.85, k = permeability at a void ratio of e'.

- (5) <u>PropertiesofWater:-</u>Theco-efficientofpermeabilityisdirectlyproportional to the unit weight of water  $(\gamma_w)$  and is inversely proportional to its viscosity( $\mu$ ). The coefficient of permeability increases with an increasethe temperature due toreductionintheviscosity.
- (6) <u>Degree of Saturation:</u> if the soil is not fully saturated, it contains air pocketformed due to entrapped air or due to air liberated from percolating water. Whatevermay be thecauseofpresence of air in soils, thepermeability is reduced due to presence of sir which causes blockage of passage. Consequently, the permeability of partially saturated soil is considerably smaller than that of fully saturated soil. In fact Darcy's Lawnotstrictly applicable to such soils.
- (7) Adsorbed Water: The fine grained soils have a layer of adsorbed waterstrongly attached to their surface. This adsorbed water layer is not free to move undergravity. It causes an obstruction to flow of water intheporesandhence reduces thepermeabilityofsoils.

It is difficult to estimate the void occupied by the adsorbed water. According to one estimate, the void ration occupied by adsorbed water is about 0.10. The effectivevoid ratio available for flow of water is thus about (e - 0.1) and not 'e'. In some cases, at very low hydraulic gradient, the coefficient of permeability of fine-grained so ils becomes negligibles mall due to presence of adsorbed water.

#### (8) ImpuritiesinWater:-

Any foreign matter in water has at enden cytop lug the flow passage and reduce the effective voids and hence the permeability of soils.

# 5.3 .1- ConstantHeadPermeability Test:-

The coefficient of permeability of a relatively more permeables oil can be determined in a laboratory by the constant-head permeability test.

- 1. Thetestisconductedinaninstrumentknownasconstant-headPermeameter.
- 2. Itconsistsofametallicmould,100mminternaldiameter,127.3mmeffectiveheighta nd1000mlcapcityaccordingtoIS:2720(PartXVII).
- 3. Themouldisprovidedwithadetachableextensioncollar,100mmdiameterand60m mhigh,requiredduringcompactionofsoil.
- 4. Themouldisprovidedwithdrainagebaseplatewithrecessforporousstone.
- $5. \quad The mould is fitted with a drain age cap having an inlet valve and an air release valve$
- 6. Thedrainagebaseandcaphavefittingsforclampingtothemould.

- 2. Thesoilsampleisplacedinsidethemouldbetweentwoporousdiscs.
- 3. Theporous discs should be at least tentimes more permeable than the soil.
- 4. Theporousdiscsshouldbedeairedbeforetheseareplacedinthemould.
- 5. Thewatertubesshouldalsobedeaired.
- 6. The sample can also be prepared in the permeameter by pour ingtheso il into it and tamping it to obtain the required density.
- 7. Thebaseisprovidedwithadummyplate,12mmthickand108mmindiameter ,whichisusedwhenthesampleiscompactedinthemould.
- 8. It is essential that the sample is fully saturated. This is done by one of the following three methods:
  - i. By pouring the soil in the permeamter filled with water and thusdepositingthesoilunderwater.
  - i. By allowing water to flow from the base to the top after the soilhasbeen placed in the mould. This is done by attaching the constant-headreservoir to the drainage base. The upward flow is maintained forsufficienttimetillalltheairhasbeenexpelledout.
  - iii. By applying a vacuum pressure of about 700mm ofmercury throughthe drainage cap for about 1.5 minutes after closing the drainagevalve. Then the soil is saturated by allowingdeaired water to enterfromdrainagebase. Theairreleasevalveiskeptopenduring saturation process.
- 9. Afterthesoilsamplehasbeensaturated,theconstant-headreservoirisconnectedtothedrainagecap.
- 10. Water is allowed to flow out from the drainage base for some time till a steady-state sestablished.

Er. ROJALI PATRA DEPT. OF CIVIL GSE, BERHAMPUR

- 11. Thewaterlevelintheconstant-headchamberinwhichthemouldisplacediskeptconstant.
- 12. The chamber is filled to the brimatthe start of the experiment.
- 13. Thewaterwhichentersthechamberafterflowingthroughthesamplespillsoverthec hamberandcollectedinagraduatedjarforconvenientperiod.
- 14. Theheadcausingflow(h)isequaltothedifferenceinwaterlevelsbetweentheconstant-headchamber.
- 15. If the cross-sectional area of the specimen is A, the discharge is given by

q=kiA or,q=k(h/l)A or,k=(ql)/(A h)

where,L=Lengthofspecimen,h=headcausingflow.

 $The discharge quise qualto the volume of water collected divided by time. \\ The finer particles of soils pecimen have at enden cytomigrate towards the end faces when wat erflows through it. This results in the formation of a filters kin at the ends. The coefficient of per meability of these end portions is quite different from that of middle portion. For more accurate eresults, it would be preferable to measure the loss of head hover a length L'in the middle to det ermine the hydraulic gradient (i). Thus <math>i=h'/L'$ .

The temperature of permeating water should be preferably somewhat higherthan that of the soil sample. This will prevent release of air during the test. It also helpsin removing the entrapped air in the pores of soil. As the water cools, it has tendency to absorbair.

Toreducethechancesofformationoflargevoidsatthepointswheretheparticles of soil touch the permeameter walls, the diameter of the permeameter is keptatleast 15to20timestheparticlessize.

Toincrease the rate of flow for the soils of low permeability, agas under pressure is applied to the surface of water in the constant-head reservoir. The total head causing flow in that case increase to  $(h+p/\gamma_w)$ , where pispressure applied.

The bulk density of the soil in the mould may be determined from the mass of soil in the mould and its volume. The bulk density should be equal to that in the field. The undisturbed sample can also be used in stead of the compacted sample. For accurate results, the specimen should have the same structure as in natural conditions.

The constant head permeability test is suitable for cleans and and gravel with  $k>10^{-2}$  mm/sec.

# 5.3.2-FallingHead/VariableHeadPermeabilityTest:-

Forrelativelylesspermeabilitysoilsthequantityofwatercollectedinthegraduatedja roftheconstant-headpermeabilitytestisverysmallandcannotbeaccurately. For such soils, the variable-head permeability test is used.teh permeametermouldisthesameasusedintheconstant-headpermeabilitytest.

1) Avertical, graduated standpipe of known diameter is fitted to the top of permeameter.

- 2) Thesampleisplacedbetweentwoporousdiscs.
- 3) The whole assembly is placed in a constant head chamber filled with water tobrimatthestartofthetest.(Seethebelowfigureshowsaschematicsketch).

- 4) Tee porous discs and water tubes be de-aired before the sample is placed. If insitu, undisturbed sample is available, the same can be used; otherwise the soil istakeninthemouldandcompactedtorequireddensity.
- 5) The valve at the drainage base (not shown in figure) is closed and vacuumpressureisappliedslowlythroughthedrainagecaptoremoveairfromthesoi
- 6) The vacuum pressure is increased to 700 mm of mercury and maintained forabout15minutes.
- 7) The sample is saturated by allowing deaired water to flow upward from thedrainagebasewhenunder vacuum.
- 8) Whenthesoilissaturated, both the top and bottom outlets are closed.
- 9) Thestandpipeisfilledwithwatertorequiredheight.
- 10) The test is stated by allowing the water in the stand pipe to flothrough thesampletoconstant-headchamberfromwhichitoverflowsandspillsout.
- 11) Asthewaterflowsthroughthesoil, the waterlevel in the standpipe falls.
- 12) The time required for the water level to fall from a known initial head  $(h_1)$  toknownasfinalhead $(h_2)$ isdetermined.
- 13) Theheadismeasuredwithreference to thelevel of water in the constant-headchamber.

Let us consider the instant when the head is h. For the infinitesimal small time dt, the head falls by dh.

Letthedischargethroughthesamplebeq.

Fromcontinuityofflow, *adh=-qdt* Where *a'* iscross-sectional area of standpipe.

Or, 
$$a dh = -(A \times k \times i) \times dtOr$$
,  $adh = -A \times k \times h/L \times dtOr$ ,  $Akdt/aL = -dh/h$ 

Integrating, 
$$\frac{AK}{aL} t^{2} dt = -f^{h2} \frac{dh}{h1}$$

$$\frac{Ak(t2-t1) = \log_{e}(h_1/h_2)}{aL}$$

$$k = Ak_{aL} \log_{e}(h/h)$$

$$1$$

Where,t=(t2-

t1), the time interval during which the head reduces from h<sub>1</sub> to h<sub>2</sub>).

Sometime 
$$k = \frac{2.30 \text{ a}}{1.\text{At}} \log_{10}(h_1/h_2)$$

Therateoffallofwaterlevelinthestandpipeandtearteofflowcanbeadjustedby changing the area of cross-section of the standpipe. The smaller diameter pipes are required for less pervious soils.

 $The coefficient of permeability is is reported at 27 ^\circ Casper IS: 2720 (Part XVII). \\$  The void ratios oil is also generally determined.

The variable head permea meter is suitable for very fines and and silt with k=  $10^{-2}$  to  $10^{-5}$  mm/sec.

Sometime, the permeability test is conducted using the consolidometer instead of the the permeameter mould. The fixed-ring consolidometer is used avariable headper meameter by attaching a stand.

## 5.4 .1-SeepagePressure:-

As water flows through the soil, it extends a force on the soil. The force acts in the direction of flows. This force is known as drag force or seepage force. The pressure induced in the soil is known as seepage pressure.

Ωr

By virtue of the viscous friction exerted on water flowing through soil energytransfer is effected between the water and soil. The force corresponding to this energytransfer is called the seepage force or seepage pressure. Thus, seepage pressure is the pressure exerted by water on the soil through which percolates.

# <u>5.4.2</u> -ThephenomenonofOuickSand:-

When flow takes place in an upward direction, the seepage pressure also acts in the upward direction and the effective pressure is reduced. If the seepage pressurebecomes equal to the pressure due to submerged weight of the soil, the effective pressure is reduced to zero, in such case, a cohesionless soil loses all its shear strength, and the soil particles have a tendency to move up in the direction of flow. This phenom enonof lifting of soil particles is called *quick condition*, boiling condition or

quicksand. Thus, during the quick condition, Er. ROJALI PATRA DEPT. OF CIVIL GSE, BERHAMPUR

$$\sigma' = z\gamma' - p_{s=0}$$
or,  $p_{s} = z\gamma'$ 
or  $iz\gamma_{w} = z\gamma'$ 

Fromwhich,  

$$I=i_c=\gamma'/\gamma_{w=G-1}$$

- ➤ Thehydraulicgradientatsuchacriticalstateiscalledhydraulicgradient. For loose deposits of sand or sand or silt, if voids ratio *e* istaken as 0.67 and G as 2.67, the critical hydraulic gradient works outto beunity.
- > Itshould benotedthat quicksand isnot a type of sandbut a flowconditionoccurringwithinacohesionlesssoilwhenitseffectivepressureis reducedtozeroduetoupwardflowofwater.

## Figure:-OUICKSANDCONDITION

- 1. The figures how saset-up to demonstrate the phenomenon of quicks and.
- 2. Waterflowsinanupwarddirectionthroughasaturatedsoilsampleofthickness'z' underahydraulichead'h'.
- 3. This head can be increased or decreased bymoving the supply tank in theupwardordownwarddirection.
- 4. When the soil particles are in the state of critical equilibrium, the total upwardforce at the bottom of soil becomes equal to the total weight of all the materials above the surface considered.

Equatingtheupwardanddownwardforcesatthelevel a-a, we have,

$$(h+z)\gamma_{wA=z}\gamma_{sat}A$$

Er. ROJALI PATRA DEPT. OF CIVIL GSE, BERHAMPUR

$$h\gamma_{w=z}(\gamma_{sat-}\gamma_w)=z\gamma'$$

$$\frac{1}{z} = i_c = \gamma'/\gamma_{w=} \frac{G-1}{1+e}$$

# 5.5.1-ConceptofFlow-Net:-

- 1. The graphical method of flownet construction, first given by Forchheimer (1930), is based on trails ketching.
- 2. Thehydraulicboundaryconditionshaveagreateffectonthegeneralshapeoftheflow net,andhencemustbeexaminedbeforesketchingisstarted.
- 3. The flow net can be plotted by trial and error by observing the properties offlownetandbyfollowingpracticalsuggestiongiven by A. Casagrande.

# Figure:-PORTIONOFAFLOWNET

## 5.5.2-PropertiesofFlow-Net:-

- 1. Theflowlinesandequipotentiallinemeetatrightanglestooneanother.
- 2. The fields are approximately squares, so that a circle can be drawn to uching all the four sides of the square.
- 3. Thequantityofwaterflowingthrougheachflowchannelissame,similarly,thesamep otentialdropoccursbetweentwosuccessiveequipotentiallines
- 4. Smallerthedimensionsofthefield,greaterwillbethehydraulicgradientandvelocity throughit.
- 5. In a homogeneous soil, every transition in the shape of the curves is smooth, being either elliptical in shape.

# 5.5.3-Application of Flow-Net:-

Aflownetcanbeutilizedforthefollowingpurposes:-

- a) Determinationofseepage.
- b) Determinationofhydrostaticpressure.

- d) Determinationofexistgradient.
- (a) <u>Determination of seepage:-</u> Figure shows a portion of flow net. The portionbetween any two successive flow lines is known as flow channel. The portion enclosedbetween two successive equipotential lines and successive flow linesis known as fieldasthatshownhatchedinthefigure

Letb&lbethewidthandlengthofthefield

Δh=headdropthroughthefield

Δq=Dischargepassingthroughtheflowchannel

H=totalhydraulicheadcausingflow=differencebetweenupstreamanddown streamheads.

b=kH ( $N_f$  /

 $N_d$ ), Where,  $N_f$  = Total number of flow channel in the net  $N_d$  = Total number of potential drops in the complete net This is required expression for the discharge passing through a flow-net and valid for isotropic soils in which  $k_x = k_v = k$ .

(b) Determination of hydrostatic pressure:- The hydrostatic pressure at anypointwithinthesoil mass is given by  $= u = \gamma_w h_w$ 

Where u = hydrostatic pressure,  $h_w$  = Pizometrichead

The hydrostatic pressure in terms of Pizometrichead  $h_w$  is calculated from the relation

 $h_{w=h-Z}$ 

Whereh=Hydraulic potential at the point under consideration.
Z= position head of the point above datum,
considered positive upwards.

(c) Determination of seepage pressure: - The hydraulic potential h at any point located after n potential drops, each value  $\Delta$  his given by

 $h=H-n\Delta h$ 

the seepage pressureatany pointequals thehydraulic potentialor balancedhydraulicheadmultipliedbyunitweightofwaterandhenceis givenby  $p_{s}=h\gamma_{w}=(H-n\Delta h)\gamma_{w}$ 

The pressure acts in the direction of flow.

(d) Determination of exist gradient:- The exit gradient is hydraulic at the downstream end of the flow line where the percolating water leaves the soil mass and emerges into the free water at the downstream. The exit gradient can be calculated from the following expression, in which  $\Delta$  h represents

the potentialdropand/theaveragelengthoflastfieldintheflownetatexitend: i\_e=(  $\Delta h/l)$  .

#### **CHAPTER-6**

# **COMPACTIONANDCONSOLIDATION**

#### **6.1 COMPACTION**

Compactionistheapplicationofmechanicalenergytoasoilsoastorearrangeitsparticlesand reduce thevoidratio.

It is applied to improve the properties of an existing soil or in the process of placing fillsuch as in the construction of embankments, road bases, runways, earth dams, andreinforced earth walls. Compaction is also used to prepare a level surface duringconstructionofbuildings. There is usually no change in the water content and in the size of the in dividual soil particles.

Theobjectivesofcompactionare:

- Toincreasesoilshearstrengthandthereforeitsbearingcapacity.
- Toreducesubsequentsettlementunderworkingloads.
- Toreducesoilpermeabilitymakingitmoredifficultforwatertoflowthrough.

#### LIGHTANDHEAVYCOMPACTIONTEST

## LaboratoryCompaction

The variation in compaction withwater content and compactive effort is first determined in the laboratory. There are several tests with standard procedures such as:

- IndianStandardLightCompactionTest(similartoStandardProctorTest)
- IndianStandardHeavyCompactionTest(similartoModifiedProctorTest)

## IndianStandardLightCompactionTest

Soiliscompactedintoa1000cm³mouldin3equallayers,eachlayerreceiving25blowsofa2.6k grammerdroppedfromaheightof310mmabovethesoil.Thecompactionisrepeatedatvariou smoisturecontents.

#### IndianStandardHeavyCompactionTest

It was found that the Light Compaction Test (Standard Test) could not reproduce the densities measured in the field under heavier loading conditions, and this led to the development of the Heavy Compaction Test (Modified Test). The equipment and procedure are essentially the same as that used for the Standard Test except that the soil is compacted in 5 layers, each layer also receiving 25 blows. The same mould is also used. To provide the increased compactive effort, a heavier rammer of 4.9 kg and agreater dropheight of 450 mm are used.

# <u>OPTIMUM MOISTURE CONTENT OF SOIL, MAXIMUM DRY</u> DENSITY, ZEROAIR VOIDLINE

To assess the degree of compaction, it is necessary to use the dryunit weight, which is an indicator of compactness of solid soil particles in a given volume. The laboratory testing is meant to establish the maximum dryden sity that can be attained for a given soil with a standard a mount of compactive effort.

Inthetest, the dryden sity cannot be determined directly, and assuch the bulk density

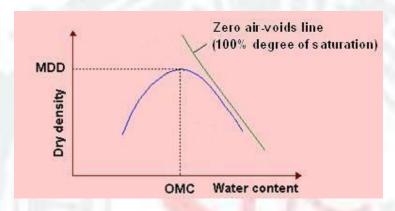

$$\gamma_d = \frac{\gamma_t}{1+w}$$

andthemoisturecontentareobtainedfirsttocalculatethedrydensityas

$$\gamma_t$$
 ,where

=bulkdensity,andw=watercontent.

Aseriesofsamplesofthesoilarecompactedatdifferentwatercontents, and acurve is drawnwit haxesofdry density and watercontent. The resulting plotusually has a distinct peak as shown. Such inverted "V" curves are obtained for **cohesive soils** (or soils with fines), and are known as compaction curves.

Drydensitycanberelatedtowatercontentanddegreeofsaturation(S)as

$$\gamma_d = \frac{G_{\text{S}} \cdot \gamma_{\text{W}}}{1 + e} = \frac{G_{\text{S}} \cdot \gamma_{\text{W}}}{1 + \frac{w \cdot G_{\text{S}}}{\alpha}}$$

Thus, it can be visualized that an increase of dryden sity means a decrease of voids ratio and a more compacts oil.

Similarly, drydensity can be related to percentage airvoids (n<sub>a</sub>) as

$$\gamma_d = \frac{(1 - n_a)G_s \cdot \gamma_w}{1 + wG_s}$$

Therelation between moisture content and dryunitweight for a saturated so ilist he **zeroair-voids line.** It is not feasible to expel air completely by compaction, no matter how much compactive effort is used and in whatever manner.

## **EffectofIncreasingWaterContent**

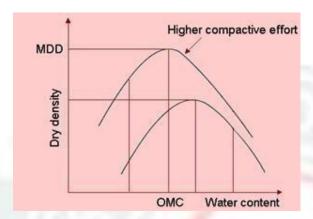

Aswaterisaddedtoasoilatlowmoisturecontents, it becomes easier for the particles to move past one another during the application of compacting force. The particles come closer, the voids are reduced and this causes the dry density to increase. As the watercontent increases, the soil particles develop larger water films around them.

This increase in dry density continues till a stage is reached where water startsoccupyingthespacethatcouldhavebeenoccupiedbythesoilgrains. Thusthewater atthis stage ehinders the closer packing of grains and reduces the dryunit weight.

The **maximum drydensity (MDD)** occurs at an **optimum water content (OMC)**, and their values can be obtained from the plot.

## **EffectofIncreasingCompactiveEffort**

The effect of increasing compactive effort is shown. Different curves are obtained for different compactive efforts. Agreater compactive effort reduces the optimum moisture content and increases the maximum dryden sity.

An increase in compactive effort produces a very large increase in dry density for soilwhenitiscompactedatwatercontentsdrierthantheoptimummoisturecontent. Its hould be noted that for moisture contents greater than the optimum, the use of heaviercompaction effort will have only a smalleffect on increasing dryunit weights.

Itcanbeseenthatthecompactioncurveisnotauniquesoilcharacteristic.Itdependsonthe compaction effort. For this reason, it is important to specify the compaction procedure(lightor heavy)whengivingvalues of MDD and OMC.

# 6.2 Factors Affecting Compaction

Thefactorsthatinfluencetheachieveddegreeofcompactioninthelaboratoryare:

- Plasticityofthesoil
- Watercontent
- Compactiveeffort

# **6.3 FIELDCOMPACTIONMETHODSANDTHEIRSUITABILITY** CompactionEquipment

Mostofthecompactioninthefieldis donewithrollers. The four most common types of rollers are

- 1. Smooth-wheelrollers(orsmooth-drumrollers)
- 2. Pneumaticrubber-tiredrollers
- 3. Sheepsfootrollers
- 4. Vibratoryrollers

Smooth-wheelrollersaresuitableforproofrollingsubgradesandfor

finishingoperationoffillswithsandyandclayeysoils. Theserollersprovide 100% coverage under the wheels, with ground contact pressures as high as 310 to 380 kN/m² (45 to 55lb/in²). They are not suitable for producing high unit weights of compaction when used onthickerlayers. Pneumaticrubber-tiredrollersarebetterinmanyrespects than the

smooth-wheelrollers. Theformer areheavilyloadedwithseveral rows oftires. Thesetiresare closely spaced—four to six in a row. The contact pressure under the tires can range from600 to 700 kN/m<sub>2</sub> (85 to 100 lb/in<sub>2</sub>), and they produce about 70 to 80% coverage.

Pneumaticrollerscanbeusedforsandyandclayeysoilcompaction. Compactionisachievedbyacom binationofpressureand kneadingaction.

Sheepsfootrollersaredrumswithalargenumberofprojections. Thearea ofeachprojectionmayrangefrom 25to 85cm²(\_4to 13in²). These rollers are most effective in compacting clayey soils. The contact pressure under the projections can range from 1400 to 7000 kN/m² (200 to 1000 lb/in²). During compaction in the field, the initial passes compact the lower portion of a lift. Compaction at the top and middle of a lift is done at a later stage. Vibratory rollers are extremely efficient incompacting granularsoils. Vibrators can be attached to smooth-wheel, pneumatic rubber-tired, or sheeps foot rollers to provide vibratory effects to the soil.

Handheldvibratingplatescanbeusedforeffectivecompactionofgranularsoilsover alimitedarea. Vibratingplates are also gangmounted on machines. These plates can be used in less restricted areas.

#### 6.4 CONSOLIDATION:

According to Terzaghi (1943), "a decrease of water content of a saturated soilwithout replacement of the water by air is called a process of consolidation." Whensaturated clayeysoils which have allow coefficient of permeability are subjected to a compressive stress due to a foundation loading, the ore water pressure

willimmediatelyincrease; however, due to the low permeability of the soil, there will be a time la gbetween the application of load and the extrusion of the pore water and, thus, the settlement.

# <u>DIFFERENCEBETWEENCOMPACTIONANDCONSOLIDATION:</u>

Consolidation and compaction are totally different process. Though both processresults a reduction in volume, it is important to know the difference between them. These are:

a. Compaction reduces volume of soil by rapid mechanical methods like tamping, rolling and vibration; whereas consolidation process reduces volume gradually bystatic, sustained loading.

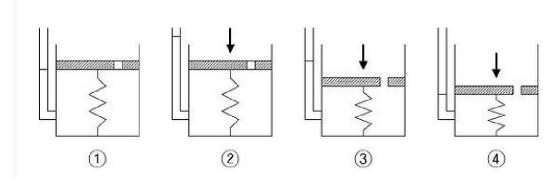

b. Compaction decreases volume by expelling air from partially saturated or drysoil; whereas consolidation process reduces volume by squeezing out water

c. Compactionisahumangeneratedpressingmethodtoproducehighunitweightof soil. Thus increasing other properties to have better founding soil. In contrast, consolidation is natural process where volume of saturated soil mass reduced by static loads from the weight of building or other structures that is transferred to soil through a foundation system.

## 6.5 SPRINGANALOGYMETHOD

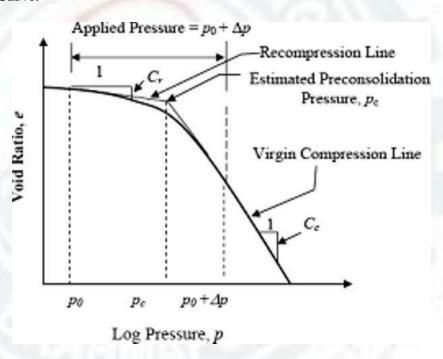

The process of consolidation is often explained with an idealized system composed of a spring, a container with a hole in its cover, and water. In this system, the spring represents the compressibility or the structure of the soil itself, and the water which fills the container represents the pore water in the soil.

Er. ROJALI PATRA DEPT. OF CIVIL GSE, BERHÄMPUR

- 1. The container is completely filled with water, and the hole is closed. (Fullysaturatedsoil)
- 2. A load is applied onto the cover, while the hole is still unopened. At this stage, only the water resists the applied load. (Development of excess pore waterpressure)
- 3. As soon as the hole is opened, water starts to drain out through the hole andthespringshortens.(Drainageofexcessporewaterpressure)
- 4. After some time, the drainage of water no longer occurs. Now, the spring aloneresists the applied load. (Full dissipation of excess pore water pressure. End of consolidation)

### Pressure-VoidRatioCurve:-

# Normally consolidated, Under consolidated and Overconsolidated soil,

Consolidation is a process by which <u>soils</u> decrease in <u>volume</u>. According to Karl vonTerzaghi "consolidation is any process which involves a decrease in water content ofsaturated soil without replacement of water by air." In general it is the process inwhich reduction in volume takes place by expulsion of water under long term staticloads. It occurs when stress is applied to a soil that causes the soil particles to packtogethermore tightly,therefore reducingits bulkvolume. When this occurs in a soil

that is saturated with water, water will be squeezed out of the soil. The magnitude of consolidation can be predicted by many different methods. In the Classical Method, developed by Terzaghi, soils are tested with an <u>oedometer test</u> to determine their compression index. This can be used to predict the amount of consolidation.

When stress is removed from a consolidated soil, the soil will rebound, regainingsome of the volume it had lost in the consolidation process. If the stress is reapplied, the soil will consolidate again along are compression curve, defined by the recom pression index. The soilwhichhaditsloadremovedisconsideredtobeoverconsolidated. This is the case for soils which have previously had glaciers on hem. The highest stress that it has been subjected is termed preconsolidationstress. Theoverconsolidation ratio or OCR is defined as the highest stresse xperienced divided by the current stress. A soil which is currently experiencing itshighest stress is said to be normally consolidated and to have an OCR of one. A soilcould be considered underconsolidated immediately after a new load is applied butbeforetheexcessporewaterpressure has hadtimetodissipate.

## AssumptionofTerzaghi'stheoryofone-dimensionalconsolidation

- 1. Thesoilishomogenous(uniformincompositionthroughout).
- 2. Thesoilisfullysaturated(zeroairvoidsduetowatercontentbeingsohigh).
- 3. The solid particles and water are incompressible.
- 4. Compressionandflowareone-dimensional(verticalaxisbeingtheoneofinterest).
- 5. Strainsinthesoilarerelativelysmall.
- 6. Darcy's Lawisvalid for all hydraulic gradients.
- 7. The coefficient of permeability and the coefficient of volume compressibility remain constant throughout the process.
- 8. Thereisauniquerelationship,independentoftime,betweenthevoidratioandeffective stress

### **CoefficientofConsolidation:**

The Coefficient of consolidation at each pressure sincrement is calculated by using the following equations:

i. Cv=0.197d2/t<sub>50</sub>(Logfittingmethod)

In the log fitting method, a plot is made between dial readings and logarithmic of time, the etime corresponding to 50% consolidation is determined

Er. ROJALI PATRA DEPT. OF CIVIL GSE, BERHÄMPUR

# ii. Cv=0.848d2/t<sub>90</sub>(Squarefittingmethod)

Inthesquarerootfittingmethod, aplotismade between dialreadings and square root of time and the time corresponding to 90% consolidation is determined.

### TimeFactor:-

The magnitude of consolidation settle ment is often calculated using Terzaghi's expressiondegree of consolidation (U) with time. Developedduringatimeoflimitedcomputingcapabilities, Terzaghi's series solution to the one-dimensional consolidation equation was generalized using a dimensionless time factor(T), where a single U-T curve is used to describe the consolidation behavior of bothsinglyanddoublydrainedstrata. Asaresult, any comparisons between one-and twoway drainage are indirect and confined to discrete values of time. By introducing amodified time factor T\* in terms of layer thickness (D) instead of the maximumdrainage path length (Hdr), it is now possible to observe the effect of drainageconditions over a continuous range of time for a variety of asymmetric initial excesspore pressure distributions. Although two separate U-T plots are (for reauired singlyanddoublydrainedcases), the time factorats pecific times remains the same for both ca ses, enabling a direct visual comparison. The importance of a revised time factor is evident w henobservingtheendpointofconsolidation, whichoccurs as Uapproaches 100%. This  $T*\cong 0.5$ two-waydrainage occursat for andat onewaydrainage, an observation not possible using the traditional expression for time factor.

## Estimation of consolidation settlements

Prediction of ground settlements have always been a big challenge for the engineersthatareresponsible for the design of subwaytunnel projects. Since ground settlem entis a crucial concept directly affecting the successfulness of a project, it must be taken seriously and should be accurately estimated.

#### CHAPTER-7

# **SHEARSTRENGTH**

#### Introduction

Soil mass when loaded may fail due to shear stress induced in it. Examples of suchfailures are sinking of soil mass under heavily loaded foundation, spalling of soilalong the edge of vertical cut, slide in an earth embankment with a steep slopemovementofbackfillbehindaweakretainingwalletc.Inalltheabovecases,thesoilfai ls essentially due to shear. When the shear stress induced in a mass of soil reacheslimiting value, shear deformation occurs, which leads to the failure of soil mass. Theresistanceofferedbythesoiltoshearisknownasshearresistance.

The maximum shearing resistance of soil against continuous shear deformation alongpotential failure plane is known as **shear strength** of soil. The plane along whichfailure of soil takes place due to sliding is known as failure plane. Failure will takeplaceontheplaneonwhichtheshearstressexceedstheshearresistance. However, if the soil has weak planes, the failure will be located in the weakest zone. Failure maynot take place along the plane of maximum shear stress, i.e., the plane which makes 45° with the principal planes.

The shearing resistance of soil is composed of two components: Normal stressdependent and normal stress independent. Examples of the above two cases are:

- 1. Frictionalresistancebetweentheparticlesatthepointofcontact
- 2. Cohesion or force of attraction between soil particles. It is characteristic of soilstateandisindependentofnormalstressacrosstheplane.

The above two components can be better understood by comparing two materials, sandandclay.

Considerable force is required to shear a block of clay as shown in the Figure 1(a) even when there is no external force acting on the block. This force is higher when the block is dry and lower with increase in water content of the soils ample. This component is called cohesion. On the other hand, if we take a sample of sandina split mould and try to shear it, the force required is practically nilwhen the reis no external norm

Er. ROJALI PATRA DEPT. OF CIVIL GSE, BERHAMPUR

alforce. Now, if we apply external normal pressure, the force

required to shear the sample increases and is proportional to the normal pressureapplied. This component is called friction.

Shear strength of the cohesionless soil results from inter granular friction as above. Plastic undrained clay does not have external friction. Hence, strength of soil results from cohesion alone. In other intermediate soils, shear strength of such soil results from internal friction as well as cohesion.

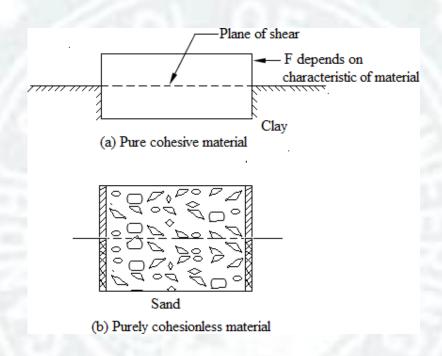

Figure 1

## Theoryoftwodimensionalstresssystem: Mohr's Stress Circle

Innumerable planes pass through each point in a soil mass. The stress components on each plane through the point depend upon the direction of the plane. It is known from strength of material that there exists three mutually perpendicular planes through apoint on which there is no shear stress and only normal stress acts. Such planes are called principal planes and the normal stresses, the principal stresses. In order of their

magnitude,thesestressesareknownasmajorprincipalstress( $\sigma_1$ ),intermediate principal stress ( $\sigma_2$ ) and minor principal stress ( $\sigma_3$ ). However, in most soil we dealwith, failure of soil mass is independent of intermediate stress. In such problems twodimensional stress analyses gives acceptable results for the solution of such failureproblems.

Consider the case of a soil element as in Figure 2 whose sides are principal planes i.e., only normal stresses are acting on the faces of the element. The stress components at apointonagive plane are given by

$$\sigma = \frac{\sigma_1 + \sigma_3 + \sigma_1 - \sigma_3 \cos 2\alpha}{2}$$

$$2 \qquad 2$$

$$\tau = \frac{\sigma_1 - \sigma_3}{2} \sin 2\alpha$$

 $where \sigma and \tau are normal stress and shear stress component on a plane in cline data nangle of \alpha with the major principal plane. \\$ 

The above results can be represented by drawing a circle with radius 
$$\sigma_1 - \sigma_3 = 0$$
. The

circle so drawn is known as Mohr's circle. Each point on the circumference of the circle gives two stress coordinates at that point on an inclined plane.

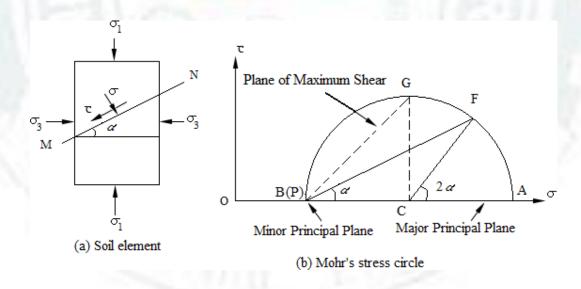

Figure2Mohr'sstresscircle

 $\label{eq:continuous} In Figure 2 (a), the major principal plane is horizontal and minor principal plane is vertical. Point A in the Mohr's circle represents the major principal stress ($\sigma_1$,0) and $B$ represents the minor principal stress ($\sigma_3$,0). To determine the stress components in a plane through the point, a point called pole is to be located on the circle. The pole is$ 

Er. ROJALI PATRA

DEPT. OF CIVIL

GSE, BERHAMPUR

 $drawn by drawing a straight line parallel to the plane on which \quad the stress conditions$ GSE, BERHÅMPUR DEPT. OF CIVIL Er. ROJALI PATRA

are known. Hence, the pole P is located by drawing ahorizontal line through the point A representing the major principal stress  $(\sigma_1)$ . The pole can also be represented by drawing avertical line through B representing minor principal plane  $(\sigma_3)$ . To know the stress on the inclined plane, a straight line PF parallel to the plane is drawnthrough the pole P. The point F on the circle gives the coordinates of the stress on the plane inclined at an angle  $\alpha$  with the direction of major principal plane. The shear stress is considered to be positive if its direction gives a clockwise moment about a point outside the wedge such as point E.

Consider another soil element as shown in Figure 3(a) in which major principal planesarenothorizontal and vertical, but are inclined to yandx-directions. The corresponding Mohr's stress circle is drawn as shown in Figure 3(b). Point Ar epresent sprincipal major principal stress  $(\sigma_1, 0)$  and minor principal stress  $(\sigma_3, 0)$ . To locate the pole, a line parallel to the major principal plane is drawn through A to intersect the circle at P. PB gives the direction of the minor principal plane. To determine the stress components on any plane MN in clinedata nangle  $\alpha$  with the major principal plane, a line making an angle of  $\alpha$  with PA is drawn through P, to intersect the circle at F. The coordinates of point F give the stress components on the plane M N.

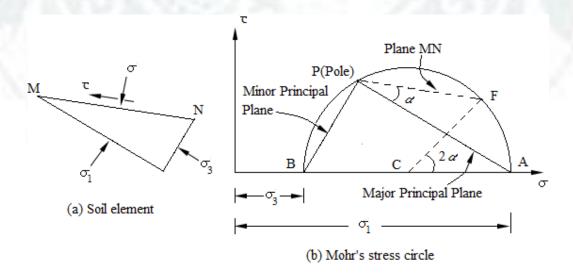

Figure3Mohr'sstresscircle

## Mohr-CoulombTheoryofFailure

Various theories of failure of soil have been proposed by many soil scientists. Ofthese, the one proposed by Coulomb and generalised by Mohr has been the mostuseful for failure problems dealing with soil and hence has got wide acceptanceamongst the soil scientists. This failure theory is known as Mohr-Coulomb failuretheory.

AccordingtoMohr,thefailureofsolialongaplanetakesplacewhentheshearstresson that plane exceeds the shear resistance of the soil. The shear resistance is a functionthenormalstress onthefailureplane.Itisexpressed as

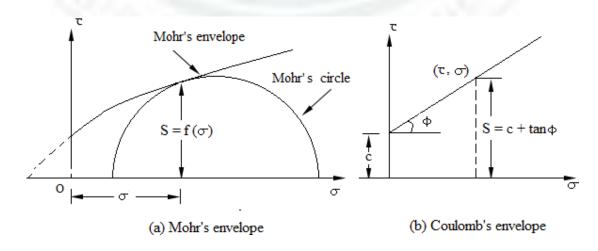

$$\tau_f = S = f(\sigma)$$

Where  $\tau_f = S$  = Shear stress at failure = Shear resistance

If the normal stress and shear stress are plotted, a curve is obtained. This curve is called the shear envelope. Coulomb assumed the relationship between  $\tau_f$  and  $\sigma$  as linear and gave the following strength equation.

$$S=C+\sigma \tan \phi$$

For most of the cases of stability of soil, Mohr's failure can be approximated as astraight line for practical purposes and thus agrees with the above strength equationgiven by Coulomb.

GSE, BERHÅ MPUR

Figure4 Er. ROJALI PATRA GSE, BERHAMPUR DEPT. OF CIVIL

Cand $\phi$ intheexpression $S=C+\sigma$ tan $\phi$ are empirical constants and are ascohesion and angle of friction or shearing resistance. In general the above constants are known as shear strength parameters.

Depending upon the nature of soil and the shear strength parameters, soils can be described as (i) cohesive soil, (ii) cohesion-less soil, and (iii) purely cohesive soil. The strengthen velopes for the three cases are shown in the Figure 5.

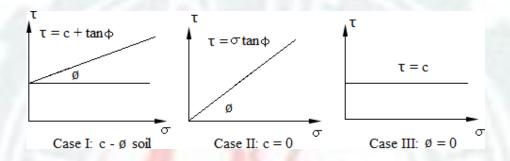

Figure 5Strengthen velopes for three types of soils

# Effectivestressprinciple

Extensive experimental studies on remoulded clays have shown the shearing strength of soil mass is controlled by the effective stress and not by the total normal stress on the plane of shear. The values of shear parameters, i.e., cohesion and angle of shearing resistance do depend upon the pore water pressure of the soil. Therefore, the Mohr-Coulombst rengthequation may be expressed in terms of effective stress.

$$\tau_f = C' + \sigma' \tan \phi'$$

 $Where \emph{c}' and \phi' are termed as effective shear parameters. Inter$ 

msoftotalstresses, the equation takes the form

$$\tau = C_u + \sigma \tan \phi_u$$

Where  $C_u$  is the apparent cohesion and  $\phi_u$  is the apparent angle of shearing resistance

Er. ROJALI PATRA DEPT. OF CIVIL GSE, BERHÅMPUR

# Determinationoffailureplane

Failure of soil may not take place along the plane of maximum shear stress. The failure will take place along the most dangerous plane called failure plane. The failure plane is the one on which the difference between shear strength and shear stress, i.e.,

 $(\tau_{T}\tau)$  is minimum. To determine the angle of failure plane with the major principal plane, let us express the normal stress  $\sigma'$  and she arstress  $\tau'$  on any plane inclined at an angle of  $\alpha$  to the major principal plane.

$$\sigma' = \frac{\sigma'_1 + \sigma'_3}{2} + \frac{\sigma_1' - \sigma'_3 \cos 2\alpha}{2}$$

$$\tau' = \frac{\sigma'_1 - \sigma'_3}{2} \sin 2\alpha$$

Theequationofshearstrengthisgivenby

$$\tau_{f} = C' + \sigma' \tan \phi'$$

$$= C' + \left[ \sigma_{1} + \sigma''_{3} + \sigma_{1} - \sigma''_{3} \right]$$

$$= \left[ \frac{1}{2} \right] \frac{1}{2} \frac{1}{2} \cos 2\alpha \left[ \frac{1}{2} \tan \phi \right]$$
So, 
$$\underline{(\tau - \tau)} = C' + \frac{\sigma'_{1} + \sigma'_{3} \tan \phi' + \sigma'_{1} - \sigma'_{3} \cos 2\alpha \tan \phi' - \sigma'_{1} - \sigma'_{3} \cos 2\alpha \cot \phi' - \sigma'_{1} - \sigma'_{2} \cos 2\alpha \cot \phi' - \sigma'_{2} - \sigma'_{2} \cos \alpha \cot \phi$$

Differentiating  $(\tau - \tau_f)$  with respect to  $\alpha$ 

$$\frac{d}{d\alpha} \int_{f} d\alpha \left(\tau - \tau\right) = -\left(\sigma' - \sigma'\right) \sin 2\alpha \tan \phi' - \left(\sigma' - \sigma'\right) \cos 2\alpha$$

$$\cos 2\alpha = -\sin 2\alpha \tan \phi'$$

$$\cot 2\alpha = \cot (90 + \phi')$$

$$\alpha = \alpha_f = 45^0 + \frac{\phi}{2}$$

 $where \alpha \textit{j} is the angle of failure plane with respect to major principal plane.$ GSE, BERHAMPUR DEPT. OF CIVIL Er. ROJALI PATRA

The above expression for location of failure plane can be directly derived from Mohr'scircleshowninFigure6.EFrepresentsthefailureenvelopegivenbythestraightline  $\tau_f = C' + \sigma' \tan \phi'$ . P is the polewith stress coordinates  $(\sigma'_{3},0)$ . The Mohr's circle is tangential to the Mohrenvelope at the point F. PF represents the direction of failure plane, incline d at an angle  $\alpha_f$  with the direction of major principal plane. From the geometry of Figure 6, we get from triangle EFK.

$$2\alpha_{j}=90+\phi'$$

$$\alpha_{f}=45^{0}+\phi'$$

$$\frac{2}{2}$$

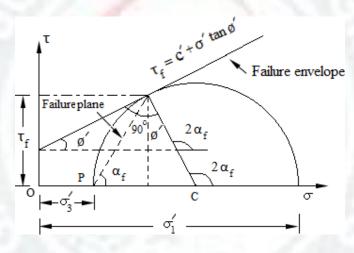

Figure6

 $It may be noted that any point on the failure envelope represents two stress components \\ \sigma' and \tau_{f} at failure. And for each \sigma' and \tau_{f}, there exists two values of principal effective stress on two principal planes for which failure takes place. It is evident from Figure 5 that \tau_{f} at failure is less than the maximum shear stress,$ 

corresponding to the point G, and acting on the plane PG. Thus the failure plane does not carry maximum shear stress, and the plane which has the maximum shear stress is not the failure plane.

## Determination of shear strength parameters

She artests are conducted on undisturbed so il sample sobtained from the field. The test results are used to plot failure en velope to determine the she ar strength

Er. ROJALI PATRA

DEPT. OF CIVIL

GSE, BERHAMPUR

parameters. It is to be noted that the shear strength parameters are fundamental properties of soil and are considered as coefficients obtained from the geometry of the strength envelope drawn by using shear test results. So, during test on saturated samples, care should be taken to simulate the field drain age condition.

Following four methods of sheartests are commonly used in the laboratory.

- 1. Directsheartest
- 2. Triaxialcompressiontest
- 3. Unconfinedcompressiontest
- 4. Vanesheartest

Basedonthedrainageconditions, the sheartests are classified as

- 1. Consolidateddrainedtest(Drainedtest/Quicktest)
- 2. Consolidatedundrainedtest
- 3. Unconsolidatedundrainedtest

#### 1. Consolidateddrainedtest

Thisisalsoknownasdrainedtest.Inthistestdrainageofwaterisallowedduringthetest. The soil sample is first consolidated fully under the normal load (in direct sheartest) or the all round pressure (in triaxial test) and the shear stress is applied slowlyenough for the water in the sample to drain away. This simulates the long termconditions in the life of a structure, i.e., the long term stability of earth dam. Theeffectivestressparameters are used.

## 2. Consolidatedundrainedtest

In this test, the soil is consolidated under the normal load or the all-round pressure butshearing is done rapidly so that drainage does not take place. This simulates the suddeneffectsduringthelifeofastructure, e.g., suddendrawdown of upstreamwater levelinane arth dam. The parameters used are  $C_u$  and  $\phi_u$ . If pore pressure measurements are made then effectives tress parameters can be used.

## 3. Unconsolidatedundrainedtest

In this case, the normal load or the all-round pressure as well as shear stress are applied under conditions of no drainage. The soil is not consolidated and shearing

is done rapidly. Therefore, effective stresses and hence the shear strength of the soil domestic density densiEr. ROJALI PATRA DEPT. OF CIVIL GSE, BERHAMPUR not get mobilised. This simulates short term failure conditions in a structure, e.g., stability of an earth dam immediately after construction. The total stress parameters are used for these cases.

### **Directsheartest**

The directshear testapparatusconsistsof(i)shearboxof squareorcircularsection,

- (ii)loadingyokeforapplyingnormalforce,(iii)gearedjackforapplyingshearforce,
- (iv) proving ring to measure shear force, and (v) strain gauges to measure horizontal displacement and vertical displacement for volume change.

The shear box consists of two halves which can slide relative to each other. The lowerhalf is rigidly held in position with the bottom of the shear box container, which slidesonrollerswhenpushedbyajackprovidedtoapplyshearforce. The gearedjack may be riveneither by electric motor or by hand. The upper half of the box is buttagainst aproving ing. The soils ample is placed and compacted in the shear box. The sample held in position betwe enapair of metal grids and porous stones or plates as shown in the Figure 7. The grid plates, provided with linear slots, are placed above the top and below the bottom of the specimen. To have proper grip with the soil specimen, the linear slots in the grid plate are aligned perpendicular to the direction of the shearing force. The soil specimen is compacted in shear box by clamping together with the help of two screws provided for the purpose. However, these screws are removed before shearing force is applied. Direct shear test may be of two types. Strain controlled shear box and stress controlled shear box. The working principles of two types of shear box are explained in the following paragraphs.

In case of strain controlled shear test a normal load N is applied on the specimen bymeansofloadingyokeandiskeptconstantthroughoutthetest. Theshearingstrainisincre ased at a constant rate by pushing the lower box through the geared jack. Themovement of lower part of the box is transmitted through the specimen to the upperpart of the box. The proving ring attached to the upper part reads the shear force F atfailure. A number of tests are conducted on identical specimens with increased normalloads and the corresponding shear force recorded. A graph is plotted between theshear force F as ordinate and the normal load N as the abscissa. The plot so obtained is

Figure 8(b) shows the failure envelope plotted as a

 $function of shear stress (\tau) and the normal stress (\sigma). The scale of both {}^{\tau and \sigma are} kept equal to me as ure the angle of shearing resistance (\phi) directly from the plot.$

# Advantagesofdirectsheartest

- 1. Directsheartestisasimpletestcomparedtothemorecomplextriaxialtest.
- 2. Asthethicknessofsampleissmall,itallowsquickdrainageand rapiddissipationofporepressureduring thetest.

# Disadvantagesofdirectsheartest

- 1. The distribution of normal stresses and shear stresses over the potential failureplane is not uniform. The stress is more at the edges and less at the centre. Hence, progressive shear failure takes place as theshear strength is notmobilised simultaneously at all points on the failure plane.
- 2. Thefailureplaneispredetermined, which may not be the weak est plane.
- 3. Theareaundersheargraduallydecreasesasthetestprogresses. The corrected area at fail ure, *A*<sub>s</sub>should be used for computing the values of normal stress σ and shear stress τ.
- 4. Thereislittlecontrolonthedrainageofporewaterofsoilascomparedtothetriaxialte st.
- Thestressonaccountoflateral restraintduetosidewallsofshearboxisnotaccountedfor inthetest.
- 6. Thereisnoprovision formeasurement of porewater pressure.

### Problem1.

From a direct shear teston undisturbed soil sample, following data have been obtained. Evaluate the undrained shear strength parameters. Determine shear strength, major and minor principal stresses and their planes in the case of specimen of sample subjected to a normal stress of  $100 \, \text{kN/m}^2$ .

Normalstress(kN/m <sup>2</sup> )			70	96	114
Shear	stress	at	138	156	170
failure(kN	$\sqrt{m^2}$				

### Solution.

Plot the shear stress versus normal stress to obtain the failure envelope keeping thescalesameforboththestresses. From the plot in Figure 9,

Theangleofshearingresistance,  $\phi = 36^{\circ}$ ; cohesion,  $c = 84 \text{ kN/m}^2$ 

The shear strength corresponding to the normal stress of 100 kN/m² is 160 kN/m². The coordinate corresponding to (100, 160) is the failure point F. Draw the Mohr's circle sothat the failure envelope is tangent to the circle at F. To do so, draw FC perpendicular to the failure envelope. With C as centre and CF as radius, draw a circle so as to intersect the normal load axis at A and B. Point A corresponds to the major principal stress  $\sigma_1$ =410kN/m² and pointBcorresponds to the minorprincipal stress

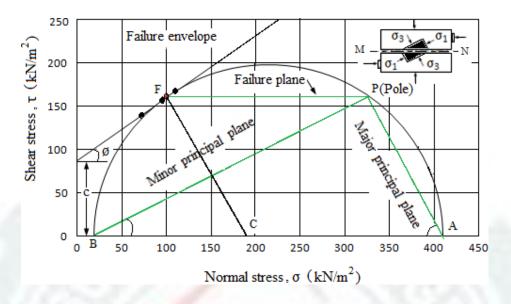

Figure9

To locate the position of the pole, draw a line FP parallel to the failure plane in theshear box (horizontal). P is the pole. PA is the direction of major principal plane whichmakes an angle 57 in the clockwise direction with the plane of shear. PB is theminorprincipal plane, making an angle of 58 in the anticlockwise direction with the planeofshearing.

## Problem2.

A sample of cohesionless sand in a direct shear test fails under a shear stress of  $160 \text{kN/m}^2$  when the normal stress is  $140 \text{ kN/m}^2$ . Find the angle of shearing resistance andtheprincipal stressatfailure.

Solution.

Plot the failure envelope passing through the origin and the point with coordinate(140,160)as

normalstressandshearstresscoordinates. The scale for both the stressaxes are kept the same.

FromtheplotintheFigure 10,

The angle of shearing resistance,  $\phi = 48.8^{\circ}$ ; cohesion, c = 0

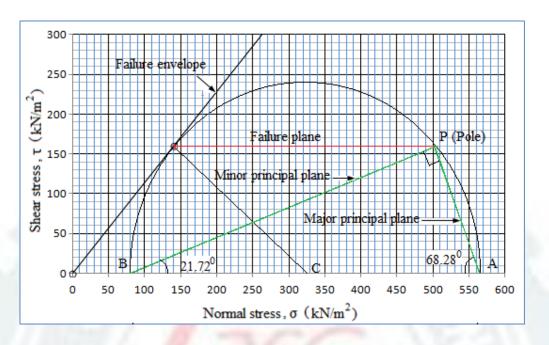

Figure 10

DrawtheMohr'scirclesothatthefailureenvelopeistangenttothecircleat F. Todoso, draw F C perpendiculartothefailureenvelope. With C ascentreand CF as radius, drawacirclesoastoi ntersect the normalloadaxisat A and B. Point A corresponds to the major principal stress  $\sigma_1 = 565...81$  kN/m² and point B corresponds to the minor principal stress  $\sigma_3 = 80.35$  kN/m².

To locate the position of the pole, draw a line FP parallel to the failure plane in theshear box (horizontal). P is the pole. PA is the direction of major principal plane whichmakes an angle  $68.28^{\circ}$  in the clockwise direction with the plane of shear. PB istheminor principal plane, making an angle of  $21.72^{\circ}$  in the anticlockwise direction withtheplaneofshearing.

### Problem3.

A cylinder of soil fails under an axial stress of 80 kN/m<sup>2</sup>. The failure plane makes anangle of 48° with the horizontal. Calculate the value of cohesion and the angle ofinternalfriction of the soil. Verify by graphical method.

Solution.

Asthereisonlyaxialstress,thereisnolateralstressactingonthesoil,i.e.,itis unconfinedcompressionfailure. Hence, minorprincipalstress princi  $\sigma_3$ =0 and major palstress  $\sigma_1$ =60.

And $\alpha$ =48<sup>0</sup>

Weknow,

 $\sigma$ = $\sigma$ tan<sup>2</sup> $\alpha$ +2ctan $\alpha$ 

1 3

80=0xtan<sup>2</sup> $\alpha$ + 2ctan48

 $80 = 2c \tan 48$ 

 $c = 36.02 \text{kN/m}^2$ 

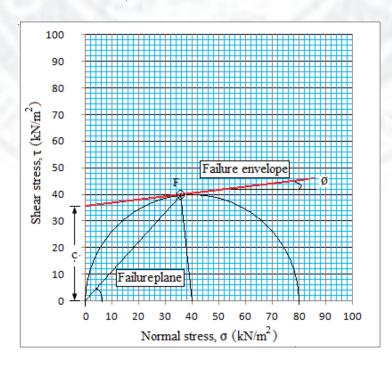

Again,

$$\alpha = 45^{0} + {}^{\phi} \frac{}{2}$$

$$\phi = (\alpha - 45)x2$$

$$\phi = (48-45)x2$$

$$\phi = 6^{0}$$

GSE, BERHAMPUR

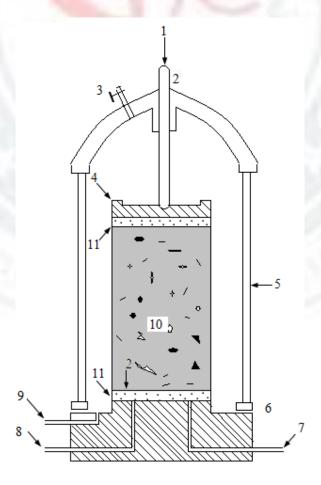

The Mohr's stress circle is drawn with radius 
$$\frac{\sigma_1 - \sigma_3}{2} = \frac{80 - 0}{2} = 40$$
. The circle passes

through theorigin representing the minor principal stress which is also the pole. Failure plane is drawn through the pole O so as to intersect the Mohr's circle at F. Join F with the centre C of the Mohr's circle. Draw the failure envelope by drawing a tangent at F on the circle so as to intersect the y-axis. The slope  $\phi = 6^{\circ}$  of the failure

plane is the angle of shearing resistance. The y-intercept  $c=36.02\ kN/m^2$  is the cohesion.

# **Triaxialcompressiontest**

Triaxialsheartestisthemostextensivelyusedforcomputationofshearstrengthparameters. In this test, the pecimen is compressed by applying all the three principalstresses,  $\sigma_1$ ,  $\sigma_2$  and  $\sigma_3$ .

# Advantagesoftriaxialcompressiontest

Followingsaretheadvantagesoftriaxialcompressiontestoverthedirectsheartest.

- Unlike the direct shear test in which the soil sample is forced to fail along apredeterminedplane, the specimen intriaxial compression is freetofail along thew eakestplane.
- 2. Distribution of stress is uniform along the failure plane is uniform. The shearstrengthismobilizeduniformlyatallpointsonthefailureplane.
- The test procedure has complete control of the drainage conditions. The fielddrainageconditionsarebettersimulatedintriaxialcompressiontestascompar ed todirectsheartest.
- 4. Precise measurements of pore pressure and volume change are possible duringthetest.
- 5. The effect of end restraint does not have considerable effect on the result asfailure usuallyoccurs nearthemiddleofthesample.

themajorprincipalstress  $\sigma_1$  till the specimentails due to shearing along a critical failure plane.

Figure 15 shows the simplest form of compression testing machine. It consists of a smallload frame fitted with a proving ring to measure the vertical stress  $\sigma_1$  applied to the soilspecimen. As eparatedial gauge is used to measure the deformation of the sample.

Thesampleisconicallyhollowedatitsendsandplacedbetweentwoconicalseatingsattache dtotwometalplates. The conical seatings reduces endrestraints and prevents the of the specimen to become barrel shaped. The load is applied through acalibratedspringbymanuallyoperatedscrewjackatthetopofthemachine. The test sample iscompressed at uniform rate of strain by the compression testing equipment. The axial deformation and the corresponding axial compressive force are measured the sample may undergo brittle failure or plastic failure. In case of brittle failure, adefinitemaximumloadisindicated by the proving ring which decreases rapidly with furthe r increase of strain. However, no definite maximum load is indicated by the proving ring dialinease of a plastic failure. In such a case, the load corresponding to 20 strain is arbitrarily taken as the failure load. The maximum axial compressivestress resisted by the specimen before failure is called the unconfined compressivestrength.

Theunconfinedcompressiontestisaquicktestinwhichnodrainageisallowed. Since  $\sigma_3 \!\!= 0 \text{ , the Mohr's circle passes through the origin, which is the pole. Figure 16 shows the stress conditions in a typical unconfined compression test. The equation plastic equilibrium may be expressed as$ 

$$\sigma_{1}=2c_{u}\tan\alpha = \begin{pmatrix} & & & \\ & c_{u}\tan & 45 & \\ & & & 2 \end{pmatrix}$$

In the above equation, there are two unknowns  $c_u$  and  $\phi_u$ , and cannot be determined by the unconfined test since a number of test on the identical specimens give the same value of  $\sigma_1$ . Hence, the unconfined compression test is generally conducted on

saturated clay for which the apparent angle of shearing resistance  $\phi_u$  = 0. Hence

$$\sigma_1=2c_u$$

The radius of the Mohr's circle is  $\sigma_{1=c}$ 

Thefailureenvelopeishorizontal.*PF* is

the failure plane, and the stresses on the failure plane are

$$\sigma = \frac{\sigma_1 q_u}{2}$$

$$\tau_f = \frac{\sigma_1}{2} = \frac{q_u}{2}$$

where  $q_u$  is the unconfined compressive strength at failure. The compressive stress

 $q = F_{u} = \frac{isc}{A_c}$  iscalculated on the basis of changed cross-sectional area  $A_c$  at failure, which

isgivenby
